Chelsey Anne Delparte, candidate for the degree of Master of Arts in Clinical Psychology, has presented a thesis titled, *Exploring Borderline Personality Disorder Features Dimensionally Among Emerging Adults with a History of Offending*, in an oral examination held on August 29, 2011. The following committee members have found the thesis acceptable in form and content, and that the candidate demonstrated satisfactory knowledge of the subject material.

External Examiner: Dr. Twyla Salm, Faculty of Education

Supervisor: Dr. Kristi Wright, Department of Psychology

Committee Member: Dr. Heather Price, Department of Psychology

Committee Member: Dr. Regan Hart-Mitchell, Adjunct

Chair of Defense: Dr. Rick Ruddell, Department of Justice Studies

*Not present at defense*
Abstract

Crime committed by emerging adults in North America is increasing, along with reports of recidivism. Although there is no known cause of offending, current literature suggests that personality pathology, specifically borderline personality disorder (BPD), may be an underlying factor, as many emerging adults entering the justice system present with emotional, cognitive, and behavioural problems symptomatic of BPD. With the latter in mind, the purposes of this study were fourfold: (1) assess for BPD features dimensionally using multiple valid measures among a male and female emerging adult sample with and without an offender history; (2) compare BPD features and associated psychopathology across both emerging adults with and without offender histories; (3) explore the relationship between BPD features, abuse history, types of criminal offenses, number of criminal offenses, and demographic information in the group with an offender history; and (4) examine potential predictors of offender status. Participants included 187 emerging adults comprising two groups; a group with a history of offending (n = 43) and a group without a history of offending (n = 144). History of offending was operationalized as a self-reported history of an arrested or charged criminal offense. Results demonstrated that BPD features, specifically affect dysregulation, negative relationships, and self-harm, were significantly more elevated in the group with a history of offending than the group without as indicated by two specific BPD measures (Personality Assessment Inventory; Borderline Evaluation of Severity Over Time). In addition, associated BPD symptomatology and psychopathology (i.e., impulsivity, paranoia, state anxiety, substance problems, and aggression) were also significantly more elevated in the group with an offender history than the group without. Participants with a
history of offending were significantly more likely to have experienced some type of abuse. Within the group with an offender history, clinical levels of BPD features were not associated with an increased history of abuse, number of arrested/charged offenses, or type of offense committed. Lastly, BPD features were a statistically significant predictor of offender status, however, the relationship was mediated by substance problems and a history of abuse. Overall, the current findings offer empirical evidence to support the notion that BPD features are more prominent among individuals with a history of offending than those without. Further, results suggest that in a heterogeneous group of participants with a self-disclosed offender history, BPD features are not associated with a specific type of offense or number of offenses. Rather, the relationship between BPD and offending may lie in the process of committing the criminal act itself rather than the type of act. Further exploration of BPD features among emerging adult offenders is required, specifically within a large incarcerated sample. Although the findings are preliminary, the current findings may have important clinical implications for both the assessment and treatment of BPD symptoms within incarcerated criminal populations.
Acknowledgements

A number of individuals contributed to the completion of this thesis by providing advice and guidance throughout the process. I would like to thank my supervisor, Dr. Kristi Wright for her support, expertise, and commitment to this project. Working with Dr. Wright has been an invaluable experience that has facilitated my growth as a researcher. In addition, I would like to express my gratitude to my committee members, Dr. Heather Price and Dr. Regan Hart, for their assistance, encouragement, and contributions to this project. I appreciate my supervisor and committee members’ dedication to the project, their recommendations, and feedback.

This research was funded by multiple sources all of which made this project possible. Acknowledgement and thanks are given to the Social Sciences and Humanities Research Council (SSHRC) for the Joseph-Armand Bombardier Canada Graduate Master’s Scholarship. This research was also supported in part by the Canadian Institute of Health Research Health Professional Student Research Award to which I am grateful. Lastly, I would like to acknowledge and express my appreciation to the Faculty of Graduate Studies and Research for their continued financial support in the form of academic scholarships, awards, and teaching assistantships.

1. Introduction

Criminality is not a rare phenomenon during emerging adulthood, defined as the period ranging from 18 years to the late 20's (Arnett, 2000). Approximately 31% of all adult criminal court cases involved emerging adults. This percentage is alarmingly disproportionate as emerging adults make up only 12% of the adult population (Statistics Canada, 2008a). In addition, emerging adults have high rates of recidivism as approximately 60% of convicted emerging adult offenders had at least one previous conviction (Statistics Canada, 2002). A specific cause for emerging adult offending is unknown; however, the empirical literature has highlighted a personality pathology (i.e., emotionally unstable personality; borderline personality disorder [BPD] features/diagnosis) that appears to be present in both adolescent/emerging adult (Alessi, McManus, Brickman, & Grapentine, 1984; Barylnik, 2003; Eppright, Kashani, Robinson, & Reid, 1993; McManus, Brickman, Alessi, & Grapentine, 1984; Taylor, James Reeves, & Kistner, 2009) and emerging adult/adult offenders (Black et al., 2007; Davison, Leese, & Taylor, 2001; Grella, Greenwell, Prendergast, Sacks, & Melnick, 2008; Jordan, Schlenger, Fairbank, & Caddell, 1996; Zlotnick et al., 2008). Specifically, identified rates of BPD features/diagnosis range from approximately 17% to 37% among adolescent/emerging adult offenders (Eppright et al., 1993; McManus et al., 1984; Taylor et al., 2009) and approximately 13% to 57% across emerging adult/adult offenders (Black et al., 2007; Blackburn & Coid, 1999; Davison et al., 2001; Dixon, Hamilton-Giachritsis, & Browne, 2008; Grella et al., 2008; Jordan et al., 1996; Logan & Blackburn, 2009; Stuart, Moore, Gordon, Ramsey, & Kahler, 2006; Timmerman & Emmelkamp, 2005; Trestman, Ford, Zhang, & Wiesbrock, 2007; Warren et al., 2002; Zlotnick, 1999;
Zlotnick et al., 2008) which is disproportionally higher than the 2% BPD prevalence rate identified in the general population (American Psychological Association [APA], 2001).

In turn, elevations in affective dysregulation/emotional instability have been observed within adolescent/emerging adult offender populations (Krischer, Sevecke, Lehmkuhl, & Pukrop, 2007; Plattner et al., 2007). In addition, a dysfunctional style of regulating emotions and impulsivity has been associated with offending during adolescence/emerging adulthood (Cooper, Wood, Orcutt, & Albino, 2003). The presence of suicidal ideation and self-harming behaviours are also common among adolescent/emerging adult offenders, with estimates of self-harm or suicidal ideation ranging from approximately 22% to 68% across studies (Alessi et al., 1984; Bailey, 1996; Holley, Arboleda-Florez, & Love, 1995; Kenny, Lennings, & Munn, 2008) which are disproportionally higher than the self-harm rate of 1% to 4% identified in the United States general population (Briere, & Gil, 1998; Klonsky, Oltmanns, & Turkheimer, 2003).

Affective dysregulation and self-harm/suicidal ideation are hallmarks of BPD along with impulsivity, instability in interpersonal relationships, and inappropriate expressions of anger (APA, 2000). Within the current literature this cluster of symptoms are frequently highlighted amongst adolescent/emerging adult offenders [i.e., affective dysregulation (Krischer et al., 2007; Plattner et al., 2007), self-harm and suicidal ideation (Alessi et al., 1984; Bailey, 1996; Holley et al., 1995; Kenny et al., 2008), inappropriate anger/aggression (Plattner et al., 2007; Wilson, Rojas, Haapanen, Duxbury, & Steiner, 2001), instability in interpersonal relationships (Krischer et al., 2007), paranoia (Krischer et al., 2007), and impulsivity (Krischer et al., 2007; Wilson et al., 2001)], and those with
a history of offending [i.e., impulsivity (Langhinrichsen-Rohling, Arata, Bowers, O’Brien, & Morgan, 2004; Pfefferbaum & Wood, 1994)]. That said, research examining the relationship between BPD symptomatology specifically and offender populations has largely focused on adult offender populations, demonstrating support for the proposed relationship.

A small number of studies have specifically examined BPD among adolescent/emerging adult offender populations, demonstrating support for the relationship between BPD and criminal behaviour (Eppright et al., 1993; McManus et al., 1984; Taylor et al., 2009). However, there are several methodological limitations to the previous studies (e.g., utilization of one measure of BPD assessment, use of dated measures, lack of comparison group, inclusion of only male offenders, utilization of only serious offenders). In addition, there is limited research on offenders in strictly the emerging adulthood period in their life course, specifically in relation to personality disorders. Undergraduate samples have been previously utilized, however the focus has been on exploration of impulsivity and suicidal behaviour among emerging adults with a self-reported history of offending, not specifically BPD features (Langhinrichsen-Rohling et al., 2004; Pfefferbaum & Wood, 1994). It is beneficial to examine BPD features and related psychopathology in relation to criminal behaviour in a non-incarcerated sample as specific symptom presentations seen in incarcerated samples may be reflective of incarceration rather than an enduring disorder (e.g., paranoia, self-harm). Incarcerated offenders may be engaging in self-harming behaviours in order to be moved to a different facility, to receive attention from staff, or to appear unstable to other incarcerated offenders. Furthermore, it has been suggested that antisocial personality disorder
(ASPD) may resemble BPD in an incarcerated setting (Vaillant, 1975). Specifically, Vaillant observed narcotic addicts that were not anxious or depressed and lacked motivation to change, transform their behaviours once incarcerated resembling patients with BPD. Vaillant discusses how defense mechanisms may shift behaviours in incarcerated settings. It is important to determine the relationship between BPD features and criminal behaviour and whether a relationship exists outside of a correctional environment. Therefore utilizing a non-incarcerated sample may provide a more accurate understanding of the link between BPD features and criminal behaviour.

To our knowledge, no study to date has specifically explored the full range of BPD features, using specific BPD measures, among an undergraduate emerging adult sample with a self-reported history of offending. Further, there is currently no research on the full range of BPD features among a non-incarcerated emerging adult male and female offender sample. Follman, Miller, and Burg (1972) demonstrated that reports of offending in undergraduates were not greatly dissimilar from incarcerated offenders. Therefore, an undergraduate sample may represent an appropriate sample for the examination of BPD features in relation to history of offending in a non-incarcerated sample. The current study aimed to examine and compare BPD features and related psychopathology, using multiple valid measures, among a heterogeneous group of male and female emerging adults with a history of offending and an emerging adult group with no history of offending. The inclusion of up-to-date multiple measures of BPD assessment will enhance support for statistically significant findings and will provide a more accurate estimate of BPD features among those with a history of offending. Furthermore, the inclusion of male and female emerging adults with a heterogeneous
history of offending (i.e., crimes range from minor offenses to major offenses) and a comparison group without a history of offending may enhance understanding of the relationship between BPD features, criminal offending, and recidivism. The inclusion of a comparison group expands the extant adolescent/emerging adult offender and emerging adult/adult offender literature on the full range of BPD features/diagnosis which has not previously included a comparison group. Lastly, the inclusion of participants strictly in the emerging adult age range is a key feature of the current study as this time period is critical given the previously noted disproportionate amount of crimes committed by this age range. It is important to examine criminal behaviour during specific stages in the lifespan (e.g., emerging adult period) in order to clarify its etiology and what facilitates maintenance and continuance of such behaviour (i.e., recidivism).

1.1 Emerging Adults

The term *emerging adulthood* is a relatively new term used to conceptualize the period from the late teens through to the late twenties (Arnett, 2000). Arnett argues that the transition from emerging adulthood to young adulthood occurs in the late twenties and is reached by age 30. Three criteria have been outlined as important milestones in reaching adult status; these criterion include accepting responsibility for oneself, making independent decisions, and becoming financially independent (Arnett, 2001). Although emerging adulthood is a relatively new term, it has become widely used in many disciplines beyond psychology (e.g., sociology, health sciences, social work, law; Arnett, 2007). Arnett (2007) postulates that the widespread use of the term *emerging adulthood* has occurred as disciplines have required new ways to conceptualize this distinct time period. Previously, Erikson (1950) described young adulthood as the period of time
ranging between 20 to 40 years and this definition dominated developmental psychology. Arnett (2007) demonstrates that norms and morals in industrialized societies have shifted since the middle of the 20th century, with widespread and longer participation in postsecondary education and training, greater tolerance of premarital cohabitation, and later ages for entering marriage (mean age = 26 years; Population Reference Bureau, 1996). Arnett (2000) demonstrated that 60% of emerging adults answered moderately (i.e., yes/no) to the question “Do you feel that you have reached adulthood”. Arnett (2007) argues that the transition to adulthood is now long enough to constitute a separate period of the life-course. Five features have been identified that distinguishes emerging adulthood from other periods: (1) it is the age of identity explorations; (2) the age of instability; (3) the self-focused age; (4) the age of feeling in-between; and (5) the age of possibilities (Arnett, 2007).

Life-course is particularly relevant when examining the course of criminal activity (i.e., how it develops and persists overtime; Moffit, 1993) and that is why the term emerging adulthood will be utilized. Within the criminal offender literature, divisions of life-course periods tend to blur (e.g., 12 to 18 years; 13 to 19 years; 18 to 54 years). The adolescent and adolescent/emerging adult offender literature is likely most representative of emerging adulthood characteristics as the mean age in emerging adult/adult studies tends to be higher than the range identified as the emerging adulthood period (e.g., mean age = 32 years; Black et al., 2007). The construct of adolescence share more characteristics with emerging adulthood, than young adulthood based on Arnett’s description. Therefore, a greater focus will be devoted to the adolescent/emerging adult literature, as few studies have focused on an emerging adult time period specifically.
1.2 Adolescent/ Emerging Adult Offenders

Adolescent offenders (under 18 years of age) in Canada are managed under the Youth Criminal Justice Act (YCJA) that was instituted in 2002 (Department of Justice Canada, 2011). The YCJA was developed on the premise that sentencing decisions should consider the offender's potential for rehabilitation. The YCJA put into place an alternative measures program developed to allow judges to hold youth accountable in the least restrictive means possible, the most restrictive sentence being secure custody. Alternative sentences include reprimand (lecture by judge), fine (maximum amount of $1000), community service, probation, intensive support and supervision order (closer monitoring and support than a probation order but still served in the community), or order to attend a non-residential program at fixed times and terms (Statistics Canada, 2008b).

The most common youth court sentence in Canada is an order of probation (59% of the time; Statistics Canada, 2008b). Depending on the criminal offense and criminal history, an adolescent may be tried as an adult in adult court. An adolescent convicted of a criminal offense may serve a sentence in an adolescent correctional facility beyond 18 years of age due to the length of his/her sentence. As a result, the age range included in many studies examining incarcerated adolescent offenders may surpass 18 years of age (e.g., age range of 12 to 20 years; Taylor et al., 2009). Alternatively, individuals serving a sentence in an adolescent correctional facility beyond 18 years of age may be transferred to an adult correctional facility.

Individuals charged with a criminal offense at 18 years of age and older are managed within the adult criminal justice system. Sentencing options in the Canadian adult criminal justice system include imprisonment in a provincial/territorial (i.e.,...
sentence is 2 years less a day) or federal institution (i.e., sentence is 2 years or more), conditional sentence served in the community under supervision with conditions restricting the movement and activities of the offender where violation can result in immediate suspension and imprisonment of the offender, probation, fine, or other sentences (e.g., restitution, compensation, absolute discharge) (Statistics Canada, 2008a). Multiple sanctions may be imposed.

1.2.1 Offenders mental health. The presence of mental disorders among offenders is high, in most cases demonstrating prevalence rates above that found in the general population (Earthrowl, O’Grady, & Birmingham, 2003). The Bureau of Justice Statistics (2006a) reported that at midyear 2005, mental health problems were present in more than half of all emerging adult/adult prison and jail inmates in the United States. Specifically, emerging adult offenders 24 years and younger had the highest rate of mental health illness; 62.6% in state prison, 57.8% in federal prison, and 70.3% in local jail (BJS, 2006a). Approximately 75% of emerging adult/adult offenders in state prison presenting with mental health problems also met criteria for substance dependence or abuse (BJS, 2006a). In addition, approximately 20% of all youth entering the justice system demonstrate mental or emotional problems, the majority with co-occurring substance use disorder (Stewart & Trupin, 2000). Teplin, Abram, McClelland, Dulcan, and Mericle (2002) examined mental disorders in a large sample of detained adolescent/emerging adult offenders (N = 1829; 10 to 18 years of age). Teplin et al. established that approximately two thirds of the male offenders and three quarters of the female offenders presented with at least one or more mental disorders (e.g., disruptive behaviour disorders, affective disorders, and substance abuse disorders). Trestman et al.
(2007) examined current and lifetime psychiatric illness among emerging adult/adult inmates (18 to 64 years of age). These authors found that 69.7% of inmates met criteria for at least one lifetime psychiatric disorder, 39.3% met criteria for multiple lifetime Axis I disorders, and 23.1% met criteria for multiple Axis II disorders.

Lifetime psychiatric disorders amongst emerging adult/adult offenders are prevalent; these include major depression (23% to 30%; BJS, 2006a; Grella et al., 2008; Gunter et al., 2008), dysthymia (3.1%; Gunter et al., 2008), affective disorders (37%; Trestman et al., 2007), mania (43% to 54%; BJS, 2006a; Gunter et al., 2008), anxiety disorders (23.9% to 43.6%; Grella et al., 2008; Trestman et al., 2007), posttraumatic stress disorder (PTSD; 11.4% to 28.6%; Grella et al., 2008; Trestman et al., 2007), panic disorder (8% to 10.4%; Grella et al., 2008; Gunter et al., 2008), psychotic disorders (1.6% to 24%; BJS, 2006a; Grella et al., 2008; Trestman et al., 2007), schizophrenia/NOS (8.4%; Gunter et al., 2008), substance abuse or dependence (73.8% to 76.6%; Gunter et al., 2008; Peters, Greenbaum, Edens, Carter, & Ortiz, 1998), attention-deficit/hyperactivity disorder (AD/HD; 21.6%; Gunter et al., 2008), Cluster A personality disorders (11.4%; Trestman et al., 2007), Cluster B personality disorders (40.7%; Trestman et al., 2007), and Cluster C personality disorders (14.1%; Trestman et al., 2007). The aforementioned prevalence rates are notably higher than the rates of the above disorders experienced in the general population (see APA, 2000). Psychological disorders amongst adolescent offenders are also common; these include major depression, AD/HD, anxiety disorders, separation anxiety disorder, posttraumatic stress disorder (PTSD), oppositional defiant disorder, conduct disorder, affective disorders, eating disorders (more common among female offenders), and substance use disorders
(Colins, Vermeiren, Schuyten, & Broekaert, 2009; Pliszka, Sherman, Barrow, & Irick, 2000; Timmons-Mitchell et al., 1997). Timmons-Mitchell et al. noted that the rates of mental disorders observed in their study were much higher than rates observed in the general population.

Parsons, Walker, and Grubin (2001) demonstrated a relationship between a diagnosis of a mental disorder among female offenders and having been remanded for a violent offence (27% females with a mental disorder versus 18% females without). The BJS (2006a) found similar outcomes as 49% of those emerging adult/adult offenders with mental health problems were charged for a violent offense as their most serious offense. Grella et al. (2008) found that adult offenders in substance abuse treatment with both Axis I and II disorders had the highest rates of prostitution or pimping, assault, homicide, and probation or parole violations, in terms of offenses committed. Furthermore, adult offenders with only Axis II pathology had the highest rates of public intoxication, illegal drug use, and possession of drug paraphernalia, in terms of offenses committed (Grella et al., 2008). Recent reports suggest that emerging adult/adult offenders with mental health issues are more likely to be injured in a fight, be charged for a physical or verbal assault, and violate facility rules during incarceration (BJS, 2006a). In addition, state prison inmates with mental health problems in the United States spend on average a maximum sentence that is five months longer than those without mental health problems (BJS, 2006a). State prison and jail inmates with mental health problems both demonstrated more prior sentences (42% to 47% had 3 or more prior sentences) compared to those without mental health problems (33% to 39% had 3 or more prior offenses) (BJS, 2006a). Overall 32% of local jail inmates and 47% of state prison inmates presenting with a
mental health problem were repeat violent offenders compared to 22% of jail inmates and 
39% of state prison inmates without mental health problems (BJS, 2006a). These 
findings suggest high levels of recidivism, particularly violent recidivism among 
offenders with mental health problems.

Additional mental health concerns among offenders include self-harming 
behaviours and suicide attempts. Self-harm and suicidal behaviours are prevalent among 
adolescent/emerging adult offenders, with estimates of self-harm or suicidal ideation 
ranging from approximately 22% to 68% across studies (Alessi et al., 1984; Bailey, 1996; 
Holley et al., 1995; Kenny et al., 2008). Kenny et al. (2008) examined self-harming 
behaviours among 242 detained adolescent/emerging adult offenders [223 male (14 to 22 
years of age) and 19 female (15 to 18 years of age)]. Of the adolescent/emerging adult 
offenders, 22% engaged in self-harming behaviours within the last 12 months. Among 
those who had engaged in self-harming behaviours, 13% reported both self-harm and 
suicide attempts. The latter is quite concerning when it has been noted that there are 
inadequate resources (e.g., time constraints, inappropriate screening conditions, lack of 
training for corrections healthcare staff, inadequate screening tools) to screen, assess, and 
treat the mental illness present in most correctional and community placement facilities 
(Birmingham, Gray, Mason, & Grubin, 2000; Birmingham, Mason, & Grubin, 1996; 
MacKinnon-Lewis, Kaufman, & Frabutt, 2002; Redding, 1999; Trupin, Stewart, Beach, 
& Boesky, 2002). Prisons are not designed to deliver mental health care as offenders are 
a highly mobile population (Birmingham et al., 1996) incarcerated in facilities thriving on 
discipline and control (i.e., anti-therapeutic environment; Hughes, 2000). In turn, the 
relationship between prisoners and prison healthcare staff may not be satisfactory
(Birmingham, et al., 2000). The BJS (2006a) reported that only 17% of local jail
inmates, 34% of state prison inmates, and 24% of federal prison inmates with mental
health problems received treatment since admission.

Potential consequences of missed mental health screening and treatment
opportunities include perpetuated pathology, repeat offending, suicide, or self-harm.
Smith and Kaminski (2010) examined self-injurious behaviours among emerging
adult/adult inmates (18 to 61 years of age). Results demonstrated that self-injurious
behaviours among inmates were associated with disproportionate utilization of health
resources and maladjustment to the correctional environment. Specifically, there was a
37% increase in the number of disciplinary incidents among inmates that self-injure.
Vollm and Dolan (2009) identified numerous needs (e.g., treatment and information
about treatment, psychological distress) among self-harming female prisoners in the
United Kingdom; more than half of those needs were unmet.

1.2.2 Offender mental health sex differences. Across studies,
adolescent/emerging adult and emerging adult/adult female offenders typically present
with more mental health problems than adolescent/emerging adult and emerging
adult/adult male offenders (BJS, 2006a; Timmons-Mitchell et al., 1997; Trestman et al.,
2007; Zlotnick et al., 2008), although some studies have demonstrated similar rates of
psychiatric disorders across sex (Gunter et al., 2008). It is important to consider the rates
of mental health disorders across sex in offender populations as differences may impact
offending and treatment needs. Trestman et al. (2007) demonstrated that one in four
women met criteria for more than one Axis II disorder and 42% had co-morbid Axis I
and II disorders. Zlotnick et al. (2008) demonstrated that significantly more female
offenders presented with a lifetime mental health disorder (i.e., eating disorders, major depression, affective disorders, anxiety disorders, and BPD) than male offenders. Male offenders presented with ASPD significantly more than female offenders. In total, 46.7% of female offenders presented with one or more disorders as compared to 24.7% of male offenders (Zlotnick et al., 2008).

Although Gunter et al. (2008) demonstrated similar rates of a current psychiatric disorders (last 12 months) across sex, female offenders presented with PTSD (23.2% females versus 10.2% males) and adjustment disorder (10.7% females versus 3% males) significantly more than male offenders. Furthermore, female offenders presented with more eating disorders including anorexia and bulimia (7.1% females versus 1.9% males) than male offenders, however this result only approached significance (p = .054; Gunter et al., 2008). Trestman et al. (2007) examined lifetime history of psychiatric disorders in male and female emerging adult/adult offenders (18 to 64 years of age). Results indicated that female offenders presented with BPD (23.2% females versus 12.9% males) and anxiety disorders (49.7% females versus 37.6% males) significantly more often than male offenders, and male offenders presented with ASPD (39.5% males versus 27% females) significantly more often than female offenders.

Numerous researchers have examined mental health needs of strictly female emerging adult/adult offenders, likely in response to the aforementioned imbalance in the presence of psychiatric disorders. Across such studies, the following rates of lifetime psychiatric disorders among female emerging adult/adult offenders have been observed: major depressive episode (MDE; 13% to 16.9%; Jordan et al., 1996; Teplin, Abram, & McClelland, 1996); dysthymia (7% to 9.6%; Jordan et al., 1996; Teplin et al., 1996);
manic episode (2.6%; Teplin et al., 1996); generalized anxiety disorder (GAD; 2.5% to 13%; Jordan et al., 1996; Logan & Blackburn, 2009; Teplin et al., 1996); panic disorder (1.6% to 26%; Jordan et al., 1996; Logan & Blackburn, 2009; Teplin et al., 1996); PTSD (33.5% to 37%; Logan & Blackburn, 2009; Teplin et al., 1996); obsessive compulsive disorder (4%; Logan & Blackburn, 2009), eating disorders (20%; Logan & Blackburn, 2009); alcohol abuse/dependence (32.3% to 38.6%; Jordan et al., 1996; Teplin et al., 1996); drug abuse/dependence (44.2% to 63.6%; Jordan et al., 1996; Teplin et al., 1996); ASPD (11.9% to 56%; Jordan et al., 1996; Logan & Blackburn, 2009; Teplin et al., 1996); and BPD (42%; Logan & Blackburn, 2009). Jordan et al. (1996) demonstrated that overall 64% of the female emerging adult/adult offenders met criteria for any lifetime disorder, and 46.3% met criteria for any current disorder.

In sum, mental health disorders are common among both adolescent and adult incarcerated offenders. It is important to further examine the level of psychopathology present in offender samples and its effect on offending. As previously noted, mental health disorders at times develop in response to an incarcerated setting. Therefore, it is important to identify mental health disorders existing among individuals with a history of offending (i.e., outside of a correctional environment) and the impact such problems may have on criminal behaviour (i.e., types of offenses committed, recidivism).

1.2.3 Types of offenses. Criminal offenses encompass both status offenses, index offenses, and non-index offenses. Status offenses are offenses considered criminal based on provincial law rather than federal law due to the person's age (under 18 years of age) at the time the crime was committed (e.g., running away from home, truancy from school, disobeying lawful commands of parents or legal guardians, liquor law violations;
Teitelbaum, 2002). Index and non-index offenses are those criminal behaviours that are considered illegal based on criminal codes and are considered violations no matter the age of the person committing them. Index offenses are divided into two subcategories: violent crimes (e.g., murder, non-negligible manslaughter, forcible rape, sexual assault, major assault, common assault), crimes against property (e.g., robbery, burglary, break and enter, automobile theft, arson) (Shoemaker, 2009; Statistics Canada, 2008a). Non-index crimes include: administration of justice crimes (e.g., fail to appear in court, breach of probation, unlawfully at large, fail to comply with order), other criminal code offenses (e.g., weapons, prostitution, disturbing the peace), criminal code traffic offenses (e.g., impaired driving), and other federal statute offenses (e.g., drug possession, drug trafficking) (Statistics Canada, 2008a). In Canada, the ten most common adolescent index and non-index offenses comprising youth court caseload in 2006/2007 include theft (14% of cases), common assault (10% of cases), break and enter (9% of cases), failure to comply with a disposition (8.5% of cases), mischief (7% of cases), possession of stolen property (6% of cases), failure to comply with order (6% of cases), major assault (6% of cases), drug possession (4% of cases), and robbery (4% of cases) (Statistics Canada, 2008b).

In Canada, the ten most common emerging adult offenses comprising adult court case loads in 2006/2007 are theft (9% of cases), common assault (8% of cases), failure to comply with order (8% of cases), impaired driving (8% of cases), breach of probation (7% of cases), drug possession (5% of cases), major assault (5% of cases), mischief (4% of cases), break and enter (4% of cases), and possession of stolen property (4% of cases) (Statistics Canada, 2008a). In total, emerging adult offenders ages 18 to 24 years
comprise 31% of all adults accused of a criminal offense, these include: 25.8% of all crimes against the person; 33.7% of all crimes against property; 32.8% of all administration of justice crimes; 34.5% of all other criminal code offenses; 23.8% of all criminal code traffic offenses; and 37.9% of all other federal statute offenses (Statistics Canada, 2008a). Emerging adults represent the highest percentage of those accused of the following crimes: attempted murder, robbery, major assault, theft, break and enter, mischief, possession of stolen property, failure to appear in court, breach of probation, failure to comply with order, possession of weapons, disturbing the peace, other criminal code traffic, drug possession, and trafficking (Statistics Canada, 2008a). For the purposes of the current study, descriptive information (i.e., frequency) regarding status offenses, index offenses, and non-index offenses will be examined specifically in relation to BPD features. Specifically, the type of offense will be explored in relation to BPD features to determine if BPD features impact the type of criminal behaviour emerging adults with a self-reported history of offending engage in.

1.2.4 Self-Reported offending. When examining the etiology of or factors related to criminal behaviour there are different methods for measuring offense history. Both self-reported offending and official crime data have their advantages and limitations. Knight, Little, Losoya, and Mulvey (2004) report that self-report criminal offense surveys provide support for the notion that official records severely underestimate the true volume of crime and that most crimes remain undetected by law enforcement personnel. In addition, Knight et al. (2004) note that many crimes detected by law enforcement personal do not lead to an official arrest and therefore are not included in official statistics. Research demonstrates that only 15% of police contacts
with adolescents (Black & Reiss, 1970), and only 14% of police contact with adults resulted in an official arrest (Worden & Myers, 1999).

In addition, official records of offending (e.g., arrest data, uniform crime reports) can be biased, possibly skewing true depictions of offending (e.g., race and sex biases; Shoemaker, 2009). Comparisons were made between self-reported adolescent offenders in the 1995 portion of the National Longitudinal Study of Adolescent Health (Add Health; Harris et al., 2003) survey and arrested offenders in the Federal Bureau of Investigation’s (FBI) Crime in the United States (CIUS; FBI, 1995) annual report (Williams, Tuthill, & Lio, 2008). Distribution of arrests were three males to one female for nonviolent crimes and six to one for violent crimes; these sex differences were not apparent in the self-report criminal offense data where males and females reported to have offended at similar rates across all types of crimes. The latter suggests that there may be biases at various levels of the legal system (i.e., tendency to arrest males more than females despite similar self-reported rates of offending) and supports utilization of self-report to obtain information regarding criminal behaviour.

Although there is support for the use of self-report to obtain information regarding criminal activity, there are numerous limitations associated with this approach (Selby et al., 2010). First, without a standard for comparison it is not possible to assess the validity of self-reported crimes (Selby et al., 2010). Second, self-report methods pose the risk of under-reporting, as individuals may not honestly report their criminal behaviour (Huizinga & Elliot, 1986). In turn, self-report also has the potential for over-reporting which has the potential to skew statistics on criminal behaviour. Lastly, self-report methods may lead to the acquisition of inaccurate information due to dishonest or
careless responding, or poor recall of events. Self-report relies on respondent’s memories of their behaviours or details of events which may be faulty. Despite these limitations, self-report of criminal activity provides the opportunity to examine the etiology of crime and criminality by allowing for the collection of more comprehensive information on individual, familial, and social/environmental characteristics and influences (Thornberry & Krohn, 2000).

1.3 Theories of Offending.

There is a strong relationship between age and crime, as the majority of crimes are committed by males aged 12 to 25 years (Gottfredson & Hirschi, 1990). Despite this statistic, a small portion (approximately ten percent) of adolescents and emerging adults commit over two-thirds of all offenses among this age group (Yoshikawa, 1994). The question is what separates those who do not engage in criminal activity from those that engage in criminal activity? Furthermore, what separates those who commit occasional minor crimes from those who engage in more lifetime criminal behaviour? The following theories of offending are the most applicable to emerging adult offenders as the theories speculate about potential causes of adolescent and/or emerging adult offending. In addition, some of the theories discuss potential factors that may influence continued criminal activity into adulthood.

1.3.1 A General Theory of Crime (GTC). Gottfredson and Hirschi (1990) propose a general theory of crime (GTC), asserting that criminal behaviour arises out of one common trait, low self-control. Low self-control is suggested to develop out of inadequate socialization and weak family bonds (e.g. poor parenting). The GTC implies that low self-control leads directly to criminal activity. The GTC speculates that criminal
behavior will decline with age due to physiological changes rendering an offender no longer able to carry out criminal activities. Low self-control itself is thought to persist over time. Although this theory and similar versions have gathered some empirical support (e.g., Simons, Simons, Chen, Brody, & Lin, 2007), the simplicity of this theory is problematic. Numerous studies have yielded results highlighting the simplicity of the GTC, suggesting that more variables (e.g. personality, biology, peer relationships, and social bonds) are involved in offending than low self-control (Cauffman, Steinberg, & Piquero, 2005; Longshore, Chang, & Messina, 2005; Simons, Wu, Conger, & Lorenz, 1994).

1.3.2 Moffitt’s Theory. Moffitt’s (1993) theory of offending focuses on behaviours prior to adolescence. Moffitt asserts that there are two types of offending, differing in regards to the etiology of criminal behaviour as well as criminal course. The first type is adolescence-limited (AL) offending and is characterized by a period of occasional criminal activity that usually ceases in early adulthood. The AL offender demonstrates no behavioural problems in infancy or childhood. Rather, criminal behaviour is proposed to begin in adolescence as goals shift towards obtaining adult possessions, power, and privileges. Moffitt makes reference to biological maturity now surpassing social maturity in society. AL offenders strive to transcend this maturity gap by demanding adult power and privileges through criminal behaviours. The second type of offending Moffitt describes is life-course-persistent (LCP) offending. The LCP offender demonstrates patterns of problem behaviours from birth (i.e., difficult temperament, ADHD, and learning disabilities) that are thought to originate from neuropsychological deficits. Furthermore, this form of adolescent offending is thought to
arise out of high risk environments (e.g., low income, single parent). A reciprocal effect is thought to occur between the high risk environment and neuropsychological deficits, as one inevitably makes the other worse. Therefore, individuals with biological predispositions and high risk social environments are at a greater risk of engaging in adolescent criminal behaviour that will likely continue into emerging adulthood and adulthood.

There is some empirical support for Moffitt's theory (e.g., Moffitt & Caspi, 2001; Moffitt, Caspi, Rutter, & Phil, 2002. However, there is no evidence that adolescents are eager to take on adult roles, power, or privileges (e.g., marriage, parenthood, and full time employment). In actuality the median age of these transitions over the past 50 years has been on the rise (Arnett, 2004) suggesting that these adult features are not actively being sought out.

1.3.3 Psychological risk factors. Shoemaker (2009) explains that the focus of psychological theories is on how psychological conditions or cognitive deficits lead to or influence criminal behaviour. Biological and environmental predispositions (i.e., learning disabilities, low impulse response, poor school performance, difficult family relationships) are acknowledged in relation to the development of a psychological condition. In turn, psychological conditions are thought to reciprocally influence biological and environmental circumstances. However, the primary focus of such theories is on how the psychological condition itself impacts or influences offending.

Although low intelligence and criminal behaviour were once thought to be directly linked (e.g., Fink, 1938), over time research has demonstrated weak support for this relationship (e.g., Sutherland & Cressey, 1978; Vold & Bernard, 1986). Rather,
more intelligent individuals may be less likely to get caught for criminal behaviours (Hirschi & Hindelang, 1977), therefore skewing perceptions of offenders. A more plausible connection between low intelligence and adolescent/emerging adult offending may be mediated by school performance, peer relationships, relationships with teachers, and withdrawal from the school system (Hirschi & Hindelang, 1977). Poor school performance has been associated with adolescent offending (Wilson & Herrnstein, 1985) and high-risk behaviours (Kasen, Cohen, & Brook, 1998). Difficulties in school alone do not entirely explain offending as high-risk behaviours can develop prior to attending school (Moffitt, 1993), but it is a plausible risk factor in the development and maintenance of criminal behaviours among adolescents and subsequently emerging adults.

1.3.4 Summary of theories of offending. Theoretical models of offending encompass a variety of disciplines and interdisciplinary systems. Theories that integrate biology, environmental factors, and psychological influences (i.e., Moffitt’s theory), appear to provide a more comprehensive understanding of the possible risk factors associated with offending. Although many theories have been proposed, to date most theories are not well supported. Parsimony may weaken any theory attempting to explain adolescent offending, as this phenomenon is a multifaceted issue. Existing research highlights a pattern of emotional dysregulation, impulse problems, aggression, interpersonal instability, and self-harm behaviours among adolescent/emerging adult offenders, behaviours consistent with BPD (e.g., Alessi et al., 1984; Bailey, 1996; Holley et al., 1995; Kenny et al., 2008; Krischer et al., 2007; Plattner et al., 2007; Wilson et al., 2001). Personality pathology itself may impact criminal behaviour across the life-span.
Moldavsky et al. (2002) examined the differences between adolescents at risk of offending (e.g., worse family circumstances) and adolescent offenders. One of the distinguishing factors between the two groups was the adolescents at risk of offending had less personality disorders and more education than the adolescent offenders. These findings lend support to the notion that personality pathology may be related to criminal behaviour.

1.4 Personality Disorders

The Diagnostic and Statistical Manual of Mental Disorders IV-Text Revision (DSM-IV-TR; APA, 2000) defines personality disorders as enduring, pervasive, inflexible patterns of inner experience and behaviour that deviates markedly from the expectations of the individual’s culture, leading to significant distress or impairment in social or occupational functioning. Livesley (2001) characterizes personality disorders as a lack of coherent sense of self, inconsistent personality attributes, maladaptive coping styles, and problems in interpersonal relationships. The DSM-IV-TR categorizes personality disorders into three clusters (i.e., Cluster A, B, and C) based on descriptive similarities. BPD is the focus of the current study and is included under Cluster B along with Antisocial, Histrionic, and Narcissistic Personality Disorders. Personality disorders are estimated to onset in late adolescence or emerging adulthood and are thought to be relatively stable over time (APA, 2000). It is estimated that personality disorders affect approximately 9% of the general population (Lenzenweger, Lane, Loranger, & Kessler, 2007). Across female emerging adult/adult offender populations, prevalence of personality disorders range from approximately 42 to 82% (Fazel & Danesh, 2002; Logan & Blackburn, 2009; Parsons et al., 2001; Von Schonfeld et al., 2006), whereas
male emerging adult/adult offenders prevalence of personality disorders is approximately 65% based on a review of 60 studies from 12 separate countries (Fazel & Danesh, 2002). Cluster B personality disorders range from approximately 32 to 56% among emerging adult/adult offender populations (Loper, Mahmoodzadegan, & Warren, 2008; Timmerman & Emmelkamp, 2005; Trestman et al., 2007). Fazel, Langstrom, Grann, & Faze (2008) examined psychopathology among adolescent/emerging adult serious offenders (15 to 21 years) finding a personality prevalence rate of 27.7% among this sample. Krischer et al. (2007) supports the assumption that personality pathology plays a major role in adolescent/emerging adult offending.

1.5 Borderline Personality Disorder

BPD is prevalent, diagnosed in approximately 2% to 6% of the general population (APA, 2000; Grant et al., 2008). In addition, BPD comprises 10% to 25% of all inpatient psychiatric admissions (Bender et al., 2001; Springer & Silk, 1996; Widiger & Weissman, 1991) and 10% to 20% of outpatients (Korzekwa, Dell, Links, Thabane, & Webb, 2008; Widiger & Weissman, 1991; Zimmerman & Mattia, 1999). Based on studies that assigned a diagnosis of BPD among adolescents/emerging adults, a BPD prevalence rate of 3% was demonstrated in a community population (9 to 19 years; Johnson, Cohen, Brown, Smailes, & Bernstein, 1999), and 43% to 53% among hospitalized inpatient samples (Becker, Grilo, Edell, & McGlashan, 2002; Grilo et al., 1998; Levy et al., 1999), albeit a diagnosis of BPD in adolescence is controversial due to the defined age of onset (i.e., 18 years). BPD is characterized by emotional dysregulation (i.e., emotionally reactive, black and white thinking, poor coping strategies), self-harm (e.g., cutting, burning), instability in interpersonal relationships, identity disturbance,
inappropriate expressions of anger, intense fears of abandonment, impulsivity, feelings of emptiness, dissociation, and paranoia (APA, 2000). According to the DSM-IV-TR (APA, 2000), five of the nine symptoms listed above must be present in order to be diagnosed with BPD. BPD is considered to be one of the most challenging personality disorders to treat as individuals with BPD are difficult to retain in therapy, often are unresponsive to therapy, and make unrealistic demands on therapists (Kiehn & Swales, 2001).

Within the current study, BPD is regarded in a multidimensional framework, an approach that has received much support (Livesley, 2001). Recent arguments suggest that a dimensional model may more accurately represent the degree of maladaptive personality traits (Livesley, 2007; Widiger & Trull, 2007) as the current criteria threshold for a diagnosis of BPD includes five of nine symptoms allowing for much heterogeneity among persons with the same disorder. Specifically, the criteria threshold for BPD (minimum of 5 out of 9 symptoms) produces over 200 variations of the disorder (Jacobo, Blais, Baity, & Harley, 2007). Examining BPD in a multidimensional framework allows focus to be directed towards the presence of BPD features and symptomatology without assigning a diagnosis of BPD. Assessing BPD features and related psychopathology along a continuum enables the examination of weak and strong presentations of BPD, diverse levels that may exert an effect on emerging adult offending uniquely. In addition, specific BPD features (e.g., emotional dysregulation, self-harming behaviour, impulsivity, aggression) can be compared between those with and without a history of offending suggesting which BPD features may be predominantly impacting the relationship between BPD features and criminal behaviour.
1.5.1 **Self-harming behaviour.** Self-harming behaviours are comprised of a wide array of behaviours including self-mutilation, suicide, suicide attempts, suicidal gestures, and parasuicidal acts (Yates, 2004). Linehan (1986) defines *parasuicidal* acts as nonfatal, intentional, self-injurious behaviour, resulting in tissue damage, illness, or risk of death. Differences present in regards to the intent, mode of injury, lethality, chronicity, and age of onset (Brown, Comtois, & Linehan, 2002; Motz, 2001). A related concept is that of suicidal ideation which involves ruminative thoughts of suicide or death. Suicidal ideation has been associated with 28 to 41% of self-harm cases (Gardner, & Cowdry, 1985; Jones, Congin, Stevenson, Straus, & Frei, 1979; Pattison & Kahan, 1983). Completion of suicide occurs in eight to ten percent of individuals with BPD (APA, 2000). It is arguably one of the most concerning symptoms associated with BPD.

1.5.2 **Inappropriate expression of anger/aggression.** Inappropriate expression of anger is another concerning BPD feature as it can lead to the infliction of harm on another individual. Current literature perceives aggressive behaviour as a dichotomous construct (Shelton, Sampl, Kesten, Zhang, & Trestman, 2009). Aggressive behaviour has been divided into premeditated aggression (i.e., instrumental, predatory, or callous and unemotional aggression) and impulsive aggression (i.e., affective, reactive, expressive, emotional, or hostile aggression). Wakai and Trestman (2008) describe impulsive aggression as a burst of rage with an inability to perceive future consequences. Shelton et al. (2009) argue that impulsive aggression is the aggression present in those with BPD. In turn, Shelton et al. acknowledges that incarcerated offenders with BPD are the most difficult to manage due to their emotional impulsivity and likelihood of self-harm.
1.5.3 Sex differences. There are significant sex differences in regards to the diagnosis of BPD across various study samples (e.g., community based and clinical samples; Maier, Lichtermann, Klinger, Heun, & Hallmayer, 1992; Zanarini et al., 1998). Overall, approximately 75% of adults diagnosed with BPD are female (APA, 2000). Black et al. (2007) demonstrated that adult female offenders were more likely than male offenders to meet criteria for BPD (55% versus 27%). Similarly, one study found prevalence rates of BPD in an adolescent/emerging adult inpatient population to be 63% for females as compared to 45% amongst males (Becker et al., 2002). Krischer et al. (2007) explored general personality pathology in three samples (i.e., detained adult males and females, incarcerated adolescents, healthy adults). There were differences in symptom presentation between sex as incarcerated adolescent/emerging adult female offenders endorsed more internalizing behaviours (e.g., self-harm and conflict in interpersonal relationships) in comparison to adolescent/emerging adult male offenders.

1.5.4 Comorbid disorders. Research demonstrates high rates of co-occurrences or co-morbidity between BPD and other Axis I (Zanarini, Frankenburg, Hennen, Reich, & Silk, 2004; Zimmerman & Mattia, 1999) and Axis II disorders (Zanarini et al., 1998). In adult samples, the most commonly co-occurring Axis I disorders were mood (e.g., major depression), anxiety (e.g., panic disorder, social phobia, and posttraumatic stress disorder), eating disorders, and substance use disorders (Zanarini et al., 2004; Zimmerman & Mattia, 1999). Zanarini et al. (2004) conducted a longitudinal study among emerging adults/adults (18 to 35 years of age) with BPD examining rates of comorbidity at a six year follow-up. Zanarini et al. found that three-quarters of patients with BPD also met criteria for a mood disorder, 60% met criteria for an anxiety disorder,
34% met criteria for an eating disorder, and 19% met criteria for a substance use disorder. Rates of co-occurring major depression and BPD are typically high, fluctuating around 61% (Zimmerman & Mattia, 1999; Zanarini et al., 2004). Zanarini et al. (1998) examined axis II comorbidity among emerging adults/adults (18 to 50 years), with dependent personality (51%) being the highest co-occurring axis II personality disorder among individuals with BPD. ASPD rates were also high at 23% in this particular study. Narcissistic personality disorder co-occurrence existed among 15% of those with BPD. There has been limited research on co-morbid rates among a strictly emerging adult sample diagnosed with BPD. However, findings in the emerging adult/adult literature allow speculation that mood, anxiety, substance, and eating disorders (i.e., Axis I disorders) may also be frequently co-morbid with BPD in strictly emerging adult populations.

1.5.5 BPD versus antisocial personality disorder. There is significant overlap in symptom presentation across the Cluster B personality disorders outlined in the DSM-IV-TR (APA, 2000). The main feature distinguishing BPD from histrionic and narcissistic personality disorder is the presence of self-harming behaviour (APA, 2000). Self-harm, however, does not necessarily distinguish BPD from ASPD which is also characterized by impulsivity, aggressiveness, and reckless disregard for the safety of self or others (i.e., potential self-harming behaviours; APA, 2000). The DSM-IV-TR differentiates the two disorders by one main feature, the goals of manipulative behaviour (i.e., self-harm). In individuals with ASPD the goals of manipulative behaviour is often driven by the goal to gain profit or power whereas the main goal of manipulative behaviour in individuals with BPD is to gain the concern of caregivers or to regulate
emotions (APA, 2000). There are sex discrepancies present between BPD and ASPD. As previously mentioned, BPD is diagnosed more often in women (75% female; APA, 2000) whereas ASPD is more likely to be diagnosed in men (80% male; Kessler et al., 1994; Robins & Regier, 1991). Zlotnick (1999) examined ASPD among incarcerated women (mean age = 31 years) while controlling for BPD and PTSD. Results suggest that self-harm/self-mutilation is a function of borderline pathology rather than a feature of ASPD among female offenders. Zlotnick et al. (1999) propose that the outcomes are a result of affect dysregulation leading to different acts in individuals with BPD (i.e., self-destructive acts) as compared to individuals with ASPD (i.e., destructive acts towards others). Complications arise when attempting to differentiate the two disorders in the context of incarceration (Vaillant, 1975). Incarcerated individuals with ASPD may, at times, strongly resemble individuals with BPD, expressing intense anger, aggression, and even suicidal behaviours (Vaillant, 1975). One must ensure that symptoms are present in numerous contexts to be diagnosed with BPD. The current study examined BPD features among emerging adults with a self-reported history of offending. Utilizing a non-incarcerated sample may aid in identifying true BPD features among those with a history of offending.

1.6 Etiological Theories of BPD

1.6.1 Attachment Theory. Attachment theories such as Bowlby’s (1979) have been applied to the development of BPD (e.g. Sable, 1997). Attachment theories focus on the significance of the parent-child bond (e.g. maternal sensitivity, proximity seeking, touching, and soothing in childhood; fostering security and autonomy in adolescence) in relation to mental health (Bowlby, 1979). A good parent-child bond is thought to lead to
the development of an enduring emotional connection between child and caregiver. The child is able to remember positive bonds when they are temporarily separated from their caregivers, indicating the development of a positive object permanence (i.e., an understanding that an object still exists even if it is no longer in sight). A poor child-parent bond (as a function of over gratification, poor maternal sensitivity, or neglect) is postulated to lead to unresolved or fearful attachment styles. The unreliable caregiver creates poor bonds. The child continuously fears rejection by the caregiver which invokes constant feelings of anxiety and anger. At this point, the child is unable to recall positive bonds during temporary periods of separation, exacerbating the child’s fear of rejection (i.e., anxiety and anger). The child may emotionally detach, a quality that becomes integrated into the individual’s personality, carrying over into adulthood. Sable (1997) indicates that this is the etiological process that facilitates the development of BPD. Although histories of family separation, neglect, physical, and/or sexual abuse are common among those with BPD (Battle et al., 2004; Johnson, Smailes, Cohen, Brown, & Bernstein, 2000; Paris, Zweig-Frank, & Guzder, 1994; Trull, 2001), this is not always the case, which suggests that additional factors play a role in the development of BPD beyond that of poor parent-child bonds.

1.6.2 Biosocial Model. A theory of BPD development that has received the most empirical support is Linehan’s (1993) biosocial model. According to this model, BPD is thought to emerge from transactions between individual biological predispositions (e.g., pre-existing emotional sensitivity) and invalidating environments (e.g., early parental abandonment, separation, loss, neglect; physical, sexual or emotional abuse). An invalidating environment is characterized by intolerance toward emotional expression,
particularly when the emotions are not context bound (Linehan, 1993). The consequence of an emotionally restrictive environment is reflected in the child's inability to understand, label, regulate, or tolerate their own emotional responses. Furthermore, the child fails to learn how to adaptively problem solve (e.g., active passivity). Linehan (1993) indicates that extreme fluctuations may occur between emotional inhibition and extreme emotional lability, a result of the invalidating environment. The emotional dysregulation experienced then becomes a pervasive personality trait (Linehan, 1993).

The primary characteristic of BPD in Linehan's model is emotional dysregulation which persists across many situations or circumstances. Dysregulation implies an accentuated sensitivity and reaction to emotional stimuli, and a slow return to emotional baseline level.

Recently, Linehan's (1993) biosocial model has been expanded to look further at trait impulsivity as a specific temperament that is biologically heritable (Crowell, Beauchaine, & Linehan, 2009). Trait impulsivity (i.e., impulsive behaviours becoming apparent during infancy as a distinguishing personality characteristic) is a proposed biological vulnerability that, in conjunction with an invalidating environment, may lead to BPD pathology (e.g., impulsive self-harming). Furthermore, it is proposed that a difficult child (i.e., difficult temperament) may exacerbate negative environmental influences, having a reciprocal effect. The expansion of the biosocial model occurred as a result of recently reported biological similarities between BPD and impulse control disorders such as ADHD (Joyce et al., 2006; Kim, Kim, & Cho, 2006). As well, impulsive behavioural traits have been found to be 80% heritable when comparing the degree of similarity in rates of impulsivity and ADHD for monozygotic and dizygotic

1.6.3 Heritability. Biology is thought to impact the development of BPD, either directly or indirectly, through a relationship with the environment. Torgersen et al. (2000) explored hereditary factors in relation to personality disorders by examining 92 monozygotic twin pairs, and 129 dizygotic twin pairs. The concordance rate for BPD was 38% among monozygotic twin pairs and 11% among dizygotic twin pairs. Using a best fitting model, it was found that there was a strong genetic component in which 69% of the variance in symptoms was accounted for by genetic effects, and 31% was accounted for by nonshared environmental effects. Congruent with these findings, Silverman et al. (1991) demonstrated in a family history study that the risk for affective instability and impulsivity was higher for the relatives of individuals diagnosed with BPD compared to relatives for those with other personality disorders or schizophrenia.

1.7 BPD Influences on Offending

Within the literature personality pathology has repeatedly demonstrated an association to criminal behaviour. Hernandez-Avila et al. (2000) examined the relationship between a personality disorder diagnosis and criminal behaviour from pre to post-treatment among drug and alcohol dependent patients. Results demonstrated that the number of personality disorders diagnosed correlated with the number of crimes against property. Further, at post-treatment and one year follow-up, a diagnosis of BPD predicted violent crimes. Warren et al. (2002) examined personality disorders among violent female prison inmates ($n = 261$) demonstrating that BPD was significantly associated with institutional violence. Personality disorders, specifically BPD, are
repeatedly shown to be associated with violent offending among emerging adult/adult offenders (De Barros & Serafim, 2008; Dixon et al., 2008; Hernandez-Avila et al., 2000; Logan & Blackburn, 2009; Ulrich et al., 2004; Warren et al., 2002; Warren & South, 2009). Sansone (2009) reviewed the literature of BPD among offenders identifying five key factors associated with BPD in offenders: (1) large portion are female; (2) history of sexual abuse; (3) committed an impulsive and violent crime; (4) ASPD traits; and (5) perpetrating domestic violence. Gandhi et al. (2001) examined personality disorders in relation to contact with the police by releasing inpatients (16 to 65 years), suitable for release, randomly into the community or hospital. There were significantly greater numbers of police contacts with increasing severity of personality disturbance. Furthermore, patients with personality disorders were six times more likely to have police contacts than those with no personality disorders.

Among the adolescent/emerging adult offender literature, the examination of BPD specifically is rare and largely conducted among serious offenders. In turn, the differentiation between violent and non-violent offenses among those adolescent/emerging adult offenders with BPD is less clearly defined. One study did examine personality disorders in a community sample and their impact on adolescent and emerging adult offending (longitudinal study 1983 to 1993; Johnson et al., 2000). Results suggest that adolescents with a greater number of Cluster A or B personality disorder symptoms were more likely than other adolescents to commit violent acts during adolescence and emerging adulthood (ages ranged from 9 to 28 years over a period of 10 years). Moldavsky et al. (2002) examined various risk factors, including psychopathology, among adolescents at risk for offending, adolescent offenders, and a
clinical sample in an attempt to differentiate the three groups. Results demonstrated that adolescent offenders had less education, significantly higher rates of disruptive and personality disorders (ADHD, conduct disorder, and BPD), and criminality than both other groups. Krischer et al. (2007) examined incarcerated adolescent/emerging adult offenders, adolescent students, and a healthy adult control group for psychopathology. Overall, higher personality disorder traits were observed among the adolescent/emerging adult offenders as compared to adolescent students, suggesting that personality pathology plays a role in adolescent/emerging adult offending. Wilson et al. (2001) examined low self-regulation (i.e., aggression, impulse control, responsibility, consideration) among incarcerated adolescent male offenders (13 to 19 years), and followed these offenders for 4.5 years post release. Among incarcerated male offenders, personality traits were predictive of positive substance abuse screen and recidivism. Specifically, low self-regulation was related to the highest rate of recidivism.

Within clinical settings, approximately 10% of adult psychiatric outpatients and 20% of adult psychiatric inpatients have received a diagnosis of BPD (Widiger & Weissman, 1991). Numerous researchers suggest that prevalence rates for BPD in adult correctional facilities are even higher than those in clinical settings (Jordan et al., 1996; McCann, Ball, & Ivanoff, 2000). BPD in the general population and in clinical settings are associated with high rates of co-morbid psychiatric disorders (Zanarini et al., 2004; Zanarini et al., 1998), heterogeneity of symptom presentation (i.e., 5 of the 9 symptoms present for BPD diagnosis produces over 200 variations; Jacobo et al., 2007), psychosocial impairment, excessive health care use, and suicide (Black, Blum, Pfohl, & Hale, 2004; Grant et al., 2008). Black et al. (2007) identified a BPD prevalence rate of 33%.
30% among an emerging adult/adult offender sample. Those who met criteria for BPD were more likely to have reported three or more current offenses, demonstrated a greater likelihood of recidivism, worse functioning overall, and higher rates of diagnostic comorbidity than adult offenders without BPD. BPD symptomatology is a serious health concern with offenders, particularly if prevalence rates are as high as the literature suggests.

1.8 BPD and Offending

As mentioned previously, the etiology of criminal offending is unclear although mental health problems have been reported extensively amongst this population. One proposed underlying construct is that of personality pathology, specifically BPD (Black et al., 2007; McManus et al., 1984; Taylor et al., 2009). Clusters of symptoms frequently highlighted among adolescent/emerging adult offenders include emotion dysregulation, self-harm/suicidal ideation, conflict in interpersonal relationships, inappropriate expressions of anger/aggression, and impulsivity (Alessi et al., 1984; Bailey, 1996; Holley et al., 1995; Kenny et al., 2008; Krischer et al., 2007; Plattner et al., 2007; Wilson et al., 2001), all of which are also symptomatic of BPD. Although research has mainly focused on the occurrence, influence, and prevalence of BPD among emerging adult/adult offenders (Black et al., 2007; Blackburn & Coid, 1999; Davison et al., 2004; Dixon et al., 2008; Grella et al., 2008; Jordan et al., 1996; Logan & Blackburn, 209; Stuart et al., 2006; Timmerman & Emmelkamp, 2005; Trestman et al., 2007; Warren et al., 2002; Zlotnick, 1999; Zlotnick et al., 2008), research among adolescent/emerging adult offenders is limited. In addition, there is no research to our knowledge on BPD among a strictly emerging adult offender sample. As mentioned previously, the mean
age range within the existing emerging adult/adult offender literature (e.g., mean age ranged from 31 to 34.8 years across studies; Black et al., 2007, Blackburn & Coid, 1999; Davison et al., 2004; Grella et al., 2008; Logan & Blackburn, 2009; Stuart et al., 2006; Timmerman & Emmelkamp, 2005; Trestman et al., 2007; Zlotnick, 1999) is beyond the emerging adult age range which includes the late teens to late 20's. These findings suggest that existing researchers have employed samples less reflective of an emerging adult sample. In addition, the characteristics of emerging adults outlined in Arnett (2000) are more reflective of adolescence than adulthood. Therefore, we will focus on those studies specifically assessing BPD amongst adolescent/emerging adult offenders. Two studies that do report BPD prevalence rates among adolescent/emerging adult offenders report BPD prevalence rates ranging from 27% to 37% (Eppright et al., 1993; McManus et al., 1984). Although both studies contribute to the literature on prevalence of BPD among an adolescent/emerging adult offender population, the diagnostic procedures are both dated (e.g., Diagnostic Interview for Borderline [DIB; Kolb, & Gunderson, 1980], DSM-III and DSM-III-R criteria). Furthermore, the relationship between BPD symptoms and adolescent/emerging adult criminal behaviour, specifically in contrast to a relevant comparison group, is not examined.

The only recent study to assess for BPD within an adolescent/emerging adult offender sample specifically examined the association between BPD traits and increased clinical and social problems among male adolescent offenders (Taylor et al., 2009). The BPD scale of the Millon Adolescent Clinical Inventory (MACI; Millon, 1993) was utilized to assess adolescent male offenders for BPD tendencies. Chart reviews were also conducted to determine history of suicidal behaviours before entering the facility and
placement on suicide watch within the facility in the last three months. Overall 17% (n = 239) of the total participants had high BPD traits, with the remaining adolescent/emerging adult male offenders serving as a control group (n = 1197). Adolescent/emerging adult offenders with high levels of BPD features displayed increased rates for both suicidal behaviours before entering the residential facility and placement on suicide watch within the last three months (chart review). The MACI demonstrated increased rates of psychopathology (i.e., depression, eating disorder features, anxiety) and worse social relations (family and peers) among those high in BPD traits as compared to the control group. Additional analysis revealed increased utilization of clinical services, higher rates of childhood sexual and physical abuse histories, and higher rates of substance dependence among those high in BPD traits as compared to the control group (i.e., adolescent male offenders without BPD in the same facility).

Although this is an important study, there are some methodological limitations (e.g., assessment of BPD features with a single measure, using only male participants, comparison to only other offenders). Furthermore, no differences were demonstrated in regards to type of criminal offense, which may have been related to the inclusion of only severe offenders. Findings may differ in a more heterogeneous offending sample.

There is limited research on offenders in strictly the emerging adulthood period. Undergraduate samples have been utilized, however, to explore features symptomatic of BPD (e.g., impulsivity, suicidal behaviour) among emerging adults with a self-reported history of offending (Langhinrichsen-Rohling et al., 2004; Pfefferbaum & Wood, 1994). Langhinrichsen-Rohling et al. examined suicidal ideation/attempts and negative affect among an undergraduate sample (n = 383) with a self-reported history of offending. Self-
reported history of offending was defined in two ways: (1) a lot of criminal acts compared to no or few criminal acts; (2) arrest history but not detained (arrest/not detained), arrest history including detainment (i.e., arrest/detained), and no arrest history. Results demonstrated that those with a history of arrest/detained had significantly higher levels of negative affect, hostility, impulsivity, and suicide prone behaviour than those without a history of arrest. Participants that were arrested/not detained demonstrated significantly higher levels of negative affect, and suicide prone behaviour as compared to those with no history of arrest. Pfefferbaum et al. (1994) examined impulsiveness in relation to undergraduates (n = 296) self-reported history of offending. Overall, thrill seeking was most strongly related to property crimes, impulsiveness was associated with interpersonal offending, and socialization was related to substance crimes.

The goal of the current study was to expand on existing research on adolescent/emerging adult offenders and undergraduate emerging adults with a self-reported history of offending. There were several methodological limitations to the most recent research (i.e., Taylor et al., 2009) on adolescent/emerging adult offending (e.g., utilization of one measure of BPD assessment, inclusion of only male offenders, utilization of only serious offenders, lack of a comparison group). Furthermore, a non-incarcerated adolescent/emerging adult sample has never been utilized to explore the full range of BPD features. It is important to examine factors that may be associated with criminal behaviour in non-incarcerated samples as these are the settings where repeat offending is likely to take place. Furthermore, an incarcerated environment has the potential to elicit behaviours that may resemble mental disorders (i.e., paranoia, self-harm) so it is important to understand the rates of mental disorders occurring outside of a
correctional setting. Vaillant (1975) suggests that specific disorders may mimic one another in an incarcerated setting, therefore in order to fully understand the impact of BPD features on offending behaviour it is essential to also examine such features among individuals with a history of offending in a non-incarcerated environment. To our knowledge, this is the first study to examine the full range of BPD features, using multiple specific BPD assessment measures, among a male and female emerging adult sample with and without a self-reported history of offending. The use of current measures of BPD assessment will provide a more accurate estimate of the prevalence of BPD features among individuals with a history of offending expanding the existing literature. The inclusion of a comparison group without a history of offending improves on the extant literature in an important way, as it moves beyond estimated prevalence rates which can be limited in terms of generalizability (e.g., inclusion of different measures, varied sample characteristics, different methods of assessment) to demonstrate whether individuals with a history of offending demonstrate more prominent BPD features than individuals without a history of offending. Direct comparisons between samples enhance our ability to examine the relationship between BPD and offending. The inclusion of a range of offenses (minor to severe) will allow for specific types of offenses to be examined in relation to BPD features which may further explain the relationship between BPD and offending. Including both male and female emerging adults in this study allowed for the exploration of sex differences in regards to BPD features among those with a history of offending which may have important treatment implications. Lastly, including a strictly emerging adult sample expands the current
literature as no study to date has examined the full range of BPD features among emerging adults with a history of offending.

Due to the difficulties in treating BPD, the severe interpersonal problems and emotional impulsivity associated with the disorder, and the extensive mental health resources utilized by this population, it is important to understand the relationship between BPD features and history of offending in both non-incarcerated (e.g., probation) and incarcerated settings. In particular, it is important to examine BPD features among emerging adults with a history of offending due to the previously noted disproportionate amount of crime committed by this age group (Statistics Canada, 2008a). Understanding criminal behaviour across the lifespan may aid in unraveling the etiology and maintenance of criminal behaviour. This knowledge may aid in decreasing recidivism rates and institutional infractions if appropriate prevention and intervention programs can be developed and implemented. Findings from this research may highlight some of the areas that should receive attention in the development and implementation of tailored assessment protocols and prevention, intervention, relapse prevention programs for incarcerated and non-incarcerated (i.e., probation) individuals.

### 1.9 Links Between BPD and Emerging Adult Offending

#### 1.9.1 Childhood maltreatment

Childhood trauma (e.g., physical, emotional, or sexual abuse, witnessing violence, neglect) is a well supported etiological correlate in BPD development. Zanarini et al. (1997) examined childhood experiences related to BPD development and demonstrated that among 358 patients with BPD, 91% reported a history of abuse and 92% reported a history of neglect prior to 18 years of age. In turn, childhood trauma histories are prevalent in emerging adult/adult (BJS, 2006a; Dietrich,
2003; Weeks & Widom, 1998) and adolescent/emerging adult offenders (Ryan & Testa, 2005). The cycle of violence theory (Walker, 1979) proposes that victims of child maltreatment are at high risk of engaging in crime, particularly violent offenses; the literature has demonstrated some support for this theory among adolescents/emerging adults and emerging adults/adults (e.g., Kakar, 1996; Smith & Thornberry, 1995; Maxfield & Widom, 1996). Fagan (2005) examined self-reported adolescent physical abuse history in relation to self-reported crime among adolescents, emerging adults, and adults using data from the National Youth Survey (9 waves; wave 1 = 11 to 17 years; wave 3 = 13 to 19 years; wave 6 = 18 to 24 years; wave 9 = 27 to 33 years). There was a significant relationship between physical abuse during adolescence and involvement in crime for all types of offenses and for all time periods. Victimization increased general offending and drug use by approximately 50%. In addition, victimization led to higher rates of serious partner violence among emerging adults (14.9% - non victims versus 46.9% - victims). Overall, 81% of victims report general offending during adolescence, 61% reported general offending during emerging adulthood, and 53.5% reported general offending in adulthood. The literature suggests that traumatic family environments contribute significantly to later criminal offending as well as type of offending (e.g., violent crimes).

In addition, childhood maltreatment has been related to personality pathology in emerging adult/adult offender samples (Christopher, Lutz-Zois, & Reinhardt, 2007; Loper et al., 2008; Warren & South, 2009; Zlotnick, 1999) and adolescent/emerging adult offender samples (Barylnik, 2003; Taylor et al., 2009). Zlotnick (1999) examined ASPD while controlling for BPD and PTSD among incarcerated emerging adults/adults (n =
There was a significant relationship between BPD and child abuse among the incarcerated female sample. In addition, adolescent/emerging adult offenders engaging in self-harming/suicidal behaviours (Kenny et al., 2008) were more likely to have traumatic childhood experiences as compared to non self-harming adolescent/emerging adult offenders. Given the above, it appears that childhood trauma may be a possible mediating factor in the proposed relationship between BPD features and adolescent, emerging adult, and adult offending. Christopher et al. (2007) examined personality pathology as a potential mediator in the association between childhood sexual abuse victimization and later sexual abuse offending against others. Overall, childhood sexual abuse was significantly related to BPD tendencies, however, personality pathology did not mediate the relationship between childhood sexual abuse victimization and later sexual abuse perpetration. Further research is needed in this area along with the examination of personality pathology as a mediator in the relationship between childhood maltreatment and criminal behaviour in general.

### 1.9.2 Substance problems.

Substance abuse is a common co-occurring disorder for individuals with BPD (Linehan et al., 1999). Substance abuse may represent a means of coping for individuals with BPD (i.e., regulating emotions) or it may strictly be the presence of a co-morbid disorder. Regardless of the reason for such co-occurrence, individuals with BPD are more likely to meet criteria for current substance abuse than individuals with any other psychiatric disorder with the exception of ASPD (Koenigsberg, Kaplan, Gilmore, & Cooper, 1985). Similarly, approximately 75% of emerging adult/adult offenders in state prison presenting with mental health problems also met criteria for substance abuse or dependence (BJS, 2006a). Drug problems (e.g.,
addiction) have been frequently reported among those with a history of offending. In the 2004 Survey of Inmates in State and Federal Correctional Facilities, approximately 32% of State prisoners and 26% of Federal prisoners indicated they had committed their current offense while under the influence of drugs (BJS, 2006b). A recent meta-analysis demonstrated that the likelihood of offending was three to four times greater for drug users than non-drug users, and that property crime (i.e., robbery, burglary, shoplifting) was the most common offense committed by drug users (Bennett, Holloway, & Farrington, 2008). Alcohol problems have also been frequently reported among individuals with a history of offending. The National Crime Victimization Survey (BJS, 2008), an American study, found that approximately 18% of victims of a violent offense perceived their offender as under the influence of alcohol. Among the 5.3 million convicted offenders under the jurisdiction of corrections agencies in 1996, approximately 36% were estimated to have been under the influence of alcohol at the time of the offense (BJS, 1998). Alcohol problems have most commonly been demonstrated among individuals convicted of public-order crimes (BJS, 1998). Based on the presence of substance problems among individuals with a history of offending and individuals with BPD, it is plausible that substance problems may be a possible mediating factor in the proposed relationship between BPD and emerging adult offending particularly if substance abuse is a coping mechanism of BPD.

1.10 Purposes

This study sought to improve on the methodological limitations of prior research (i.e., Taylor et al., 2009) among a strictly emerging adult sample. Specifically, the current study aimed to examine BPD features using multiple valid measures, among male
and female emerging adults comprising two groups: emerging adults with a heterogeneous history of offending (e.g., history of minor to severe offenses) and a comparison group of emerging adults without a history of offending. It is important to understand factors involved in offending among an emerging adult sample due to the high rates of criminal offenses committed by this age group (BJS, 2006a). In turn, examination of BPD characteristics in relation to criminal behaviour in a non-incarcerated sample is beneficial as certain symptom presentations seen in incarcerated samples may be reflective of incarceration rather than an enduring disorder that have the potential to mimic BPD symptoms (e.g., paranoia). Furthermore, it has been suggested that ASPD may mimic BPD in an incarcerated setting (Vaillant, 1975) and therefore utilizing a non-incarcerated sample may provide a more accurate understanding of the link between BPD and criminal behaviour. The purposes were fourfold: (1) assess for BPD features dimensionally using multiple valid measures (i.e., Personality Assessment Inventory; PAI; Morey, 1991; Borderline Evaluation of Severity Over Time; BEST; Pfohl & Blum, 1997; Beck Scale for Suicide Ideation; BSS; Beck, Steer, & Ranieri, 1988; Barratt Impulsiveness Scale-11; BIS-11; Patton, Stanford, & Barratt, 1995) among a heterogeneous male and female emerging adult sample with and without a history of offending; (2) compare BPD features and associated psychopathology across emerging adults both with and without a history of offending; (3) explore the relationship between BPD features, abuse history, type/number of offenses, and demographic information (e.g., ethnicity, sex, age, education level) in the group with an offender history; and (4) examine potential predictors (i.e., BPD features) of offender status.

1.1 Hypotheses
It was hypothesized that:

(1) BPD features would be significantly more elevated in the emerging adult group with an offender history than the group without an offender history as measured by the BEST subscales scores (i.e., affect, negative behaviours), PAI-Borderline Features scale (PAI-BOR) and PAI-BOR subscales (Affective Instability; BOR-A; Identity Problems; BOR-I; Negative Relationships; BOR-N; Self-Harm; BOR-S);

(2) specific BPD symptomatology and associated psychopathology would be significantly more elevated in the emerging adult group with an offender history than the group without an offender history as measured by the BIS-11 (i.e., impulsivity), BSS (self-harm/suicidal ideation), Center for Epidemiological Studies Depression Scale (CES-D; Radloff, 1977) (i.e., depression), State Trait Anxiety Inventory for Adults – Form Y (STAI; Spielberger, Gorsuch, Lushene, Vagg, & Jacobs, 1983) (i.e., state and trait anxiety), PAI clinical scales and subscales (i.e., somatic complaints, anxiety, anxiety-related disorders, depression, mania, paranoia, schizophrenia, antisocial features, alcohol problems, drug problems), and three specific PAI treatment scales and subscales (i.e., aggression, suicidal ideation, stress);

(3) the group with an offender history would have, on average, scores in the clinical range for specific BPD associated psychopathology as measured by relevant PAI clinical scales (i.e., alcohol problems, drug problems, anxiety, depression, paranoia) and two of the PAI treatment scales (i.e., aggression, suicidal ideation);

(4) within the group with an offender history, BPD features would be associated with an increased history of abuse (i.e., emotional, physical, sexual);
(5) within the group with an offender history, BPD features would be associated with a greater number of offenses;

(6) sex differences would be found among our group with an offender history; specifically, we expected to find significantly higher BPD features among emerging adult females with offender histories as compared to emerging adult males with offender histories as measured by the BEST subscales (i.e., affect, negative behaviours), and PAI Borderline Features scale and subscales; and

(7) BPD features would be predictive of group membership (i.e., group with offender history versus group without offender history).

2.0 Method

2.1 Participants

Participants included emerging adults (18 to 26 years of age) from the University of Regina (Regina, Saskatchewan), Saskatchewan Institute of Applied Science and Technology (SIAST; Regina, Saskatchewan), and Adult Campus (Regina, Saskatchewan). Participants comprised two groups: those emerging adults with a history of offending and those without a history of offending as identified via a self-report offending questionnaire. For the purposes of this research, a history of offending is operationalized as a history of an arrested or charged offense. The age range of 18 to 26 years was selected for this study on the basis that emerging adulthood ranges through to the late twenties. In addition, this age range is representative of an undergraduate university population and is appropriate for norm comparisons and reliability of the measures included in this study.
SIAST is a post-secondary institute that provides technical education and skills training in various fields. Adult Campus is a facility that allows emerging adults (18 to 21 years) who have not completed high school academics to complete a high school program or upgrade courses. Participants from SIAST and Adult Campus were recruited through research posters displayed at each of the locations. SIAST and Adult Campus participants were entered in a draw for a $50 Best Buy gift certificate as a token of appreciation for participating in the study. University of Regina participants were recruited through the psychology participant pool. Students recruited through the psychology participant pool were given a 2% course credit for two hours of participation. The use of the research participant pool to recruit participants in return for course credit is a common practice in psychological research. Ethical approval for this research was obtained from the University of Regina Research Ethics Board (Appendix A).

2.2 Measures

All measures were administered anonymously online via Survey Monkey. Survey Monkey is a web-survey company that is located in the USA. This company is subject to U.S. laws; in particular, the US Patriot Act that allows authorities access to the records of internet service providers. Survey Monkey's servers record incoming IP addresses - including that of the computer that is used to access the survey. However, no connection is made between participant responses and computer's IP addresses.

Consent (Appendix B) was obtained on-line in a non-controlled setting (i.e., home computer, university computer, personal lap top). Following consent, basic demographic information (i.e., ethnicity, sex, age, education level, relationship status, employment status, current household income, current living arrangements, parents relationship status)
and abuse history (i.e., emotional, physical, sexual abuse) were obtained from participants through a basic demographic form (Appendix C). Offending history (e.g., types of criminal offenses, number of criminal offenses) was obtained from participants through a self-report offending form.

2.2.1 Self-Report of Offending-Revised (Appendix D). The SRO-R was developed for this study based on the Self-Report of Offending (SRO) utilized in the Project on Human Development in Chicago Neighborhoods (PHDCN; Earls et al., 2002). The SRO was adapted from the Self-Report of Delinquency scale (SRD; Elliott & Huizinga, 1989) which has demonstrated acceptable reliability and validity across studies (Jolliffe et al., 2003; Thornberry & Krohn, 2000). Items 3 to 32, 34F, 34G, 35, and 36 of the SRO were included in the SRO-R, with four additional items added. The course of questions was altered, inquiring beyond contact with police to include a series of questions regarding convictions and sentencing. The time frame inquired about in regards to the offenses was also altered to assess for lifetime criminal involvement. SRO-R items include questions about criminal activities such as theft, violence, and substance use (i.e., index and non-index offenses). The SRO-R is divided into two sections, the first inquiring about specific criminal activity and the second asking general questions regarding criminal involvement. The SRO-R does not include specific questions regarding status offenses, however, specific status offenses (i.e., drinking under the legal age limit) may be reported in section II of the SRO-R which inquires about a history of criminal offenses in an open format. The SRO-R served as the self-report offending questionnaire utilized in this study to assess for a history of offending.
2.2.2 Personality Assessment Inventory (Appendix E; PAI; Morey, 1991).

The PAI is a 344-item self-report questionnaire designed to assess a variety of clinical constructs (i.e., personality and psychopathology). Each item is rated on a 4-point scale (i.e., 0 to 3) with responses ranging from false to very true. Each response holds a specific weight. The items make up 22 non-overlapping full scales: 4 validity scales, 11 clinical scales (ten of which have conceptual subscales), 5 treatment scales, and 2 interpersonal scales. Raw scores are transformed into standardized T-scores which are compared to a large normative sample. T scores greater than or equal to 70 represent a pronounced deviation from typical responses of adults in the normative sample. The PAI clinical scale of primary focus is the borderline features scale (PAI-BOR) which contains four subscales that look at characteristics or traits such as unstable interpersonal relationships (negative relationships, BOR-N), impulsive acts or self-harm behaviours (BOR-S), emotional dysregulation (affective dysregulation, BOR-A), and identity disturbance (BOR-I). Elevations (T ≥ 70) on these scales are indicative of a high level of BPD features. Additional PAI clinical scales (i.e., Anxiety, Depression, Alcohol Problems, Drug Problems) and treatment scales (i.e., Suicidal Ideation, Aggression) were examined in order to assess associated BPD symptomatology and psychopathology.

The PAI has demonstrated good reliability and validity (Morey, 1991). The PAI full scales demonstrated good internal consistency (α = .81 to .86) for normative, college, and clinical samples. Validity studies demonstrated the convergent and discriminant validity of PAI scales with more than 50 other measures of psychopathology. Recent research has shown the PAI to be a useful tool in distinguishing patients with a diagnosis of BPD from patients without, and is correlated with BPD diagnosis as determined by
SCID-II structured clinical interviews (Jacobo et al., 2007; Kurtz & Morey, 2001). The PAI-BOR scale is correlated with other borderline inventories including the MMPI Borderline scale ($r = .77$), the Bell Object Relations Inventory insecure attachment scale ($r = .63$), and the NEO-Personality Inventory neuroticism scale ($r = .67$) demonstrating good concurrent validity (see Morey, 1996). Cronbach’s alpha coefficients were calculated for the overall sample indicating good reliability for the set of items on the PAI-BOR ($\alpha = .90$).

2.2.3 Borderline Evaluation of Severity Over Time (Appendix F; BEST; Pfohl & Blum, 1997). The BEST evaluates both the severity and change of symptoms in clients with BPD. The BEST is a self-report questionnaire consisting of 15 items each rated on a 5-point scale (i.e., 1 to 5). Scores range from 12 to 72. The degree of impairment from nine BPD criteria over the previous week is rated. Three subscales comprise the BEST. Subscale A (e.g., negative thoughts and feelings) and Subscale B (e.g., negative behaviours) represent the core symptoms of BPD, and are examined based on level of distress over a one week period. Subscale C (e.g., positive behaviours) is a subscale related to treatment compliance, and is reported based on frequency of occurrence over a one week period. High BEST total scores (>39) suggest moderate to high rates of BPD symptoms. The BEST total score demonstrated excellent internal consistency ($\alpha = .90$), and moderate test-retest reliability ($r = .62$) (Blum, Pfohl, St. John, Monahan, & Black, 2002; Pfohl et al., 2009). Blum et al. (2002) indicates that the BEST is moderately correlated ($r = .63$) with the Positive and Negative Affectivity Scale (PANAS; Watson, Clark, & Tellegen, 1988) indicating concurrent validity. The BEST is thought to be a useful tool in the evaluation and initial screening of BPD symptoms.
(Blum et al., 2002). Subscale C was not utilized in this study as the emerging adult sample was not a clinical sample and therefore a limited number of the participants experienced treatment. Subsequently, a BEST total score was not reported rather the focus remained on BEST subscales A and B which directly examine BPD features. Cronbach’s alpha coefficients were calculated for the overall sample indicating good reliability for the set of items on the BEST A (α = .85) and moderate reliability for the set of items on the BEST B (α = .64).

2.2.4 Beck Scale for Suicide Ideation (Appendix G; BSS; Beck, Steer, & Ranieri, 1988). The BSS is a concise (21-item) self-report version of the Scale for Suicide Ideation (SSI; Beck, Kovacs, & Weissman, 1979) that assesses suicidality (e.g., suicide risk, suicidal thoughts, suicide behaviours) in adolescents and adults. All items are responded to on a 3-point (0 to 2) Likert scale where individuals are to indicate which statement best describes how they have been feeling over the past week, including the current day. When scoring, 19 of the 21 items are used in scoring and the remaining two items are used strictly as indicators of previous suicide attempts. The first five items serve the purpose of an initial screen for suicidal ideation. Total scores range from 0 to 48 (screening items included), with 24 being the suggested cut off (sensitivity 100%, specificity 100%) score indicative of suicidality (Cochrane-Brink, Lofchy, & Sakinofsky, 2000). In the current study, any score above zero was examined as any positive score may be an indicator of suicidality. The BSS demonstrates good validity and excellent internal consistency (α = .87 to .90), in both inpatient and outpatient samples (Beck & Steer, 1991), and an undergraduate sample (α = .90; Van Orden, Witte, Gordon, Bender, & Joiner, 2008). Test-retest reliability is moderate (r = .54) in a sample of 60 adults over
a one week period (Beck & Steer, 1991). Cronbach’s alpha coefficient was calculated for the set of items on the BSS, indicating moderate reliability ($\alpha = .61$).

2.2.5 Barratt Impulsiveness Scale - Version 11 (Appendix H; BIS-11; Patton, Stanford, & Barratt, 1995). The BIS-11 was developed to evaluate the personality and behavioural construct of impulsiveness. The BIS-11 is reported to be the most commonly administered self-report measure for assessment of impulsiveness in research and clinical settings across a variety of disorders (substance use disorder, mood disorders, AD/HD, suicidal behaviours, Axis II disorders) and populations (e.g., forensic populations; a summary is provided in Stanford et al., 2009). The BIS-11 is a self-report measure consisting of 30-items each rated on a 4-point scale (i.e., 1 to 4) with responses ranging from rarely/never to almost always/always. Patton et al. (1995) demonstrated that the BIS-11 Total Score is comprised of three second-order factors/subscales (i.e., Motor Impulsiveness, Nonplanning Impulsiveness, Attentional Impulsiveness) and six first-order factors/subscales (i.e., Attention, Motor, Self-control, Cognitive Complexity, Perseverance, Cognitive Instability). The literature suggests a cut off score of 72 indicating high impulsiveness, with scores ranging from 52 to 71 indicating normal limits of impulsiveness (Stanford et al., 2009). Scores below 52 are reported to be indicative of extremely over controlled individuals, or individuals who have responded in a dishonest manner. The BIS-11 total score demonstrated good internal consistency ($\alpha = .83$), and test-retest reliability ($r = .83$) (Stanford et al., 2009). In addition, the BIS-11 three second-order subscales demonstrated adequate to good internal consistency ($\alpha = .59$ to .74) and test re-test reliability ($r = .61$ to .72). The BIS-11 is highly correlated with similar self-report measures of impulsivity: the Eysenck Impulsiveness Scale (Eysenck

51
specifically the Impulsiveness subscale ($r = .63$, $p < .001$); and three of the four subscales of the Zuckerman Sensation-Seeking Scale (Zuckerman, Eysenck, & Eysenck, 1978) ($r = .24$ to .39) demonstrating convergent validity (Stanford et al., 2009). Cronbach's alpha coefficient was calculated for the overall sample indicating good reliability for the set of items on the BIS-11 ($\alpha = .84$).

2.2.6 Center for Epidemiological Studies Depression Scale (Appendix I; CES-D; Radloff, 1977). The CES-D is a 20-item self report measure that assesses for the presence of depressive feelings and behaviours over a one week period. Items included in the CES-D are comprised of symptoms associated with depression (e.g., depressed mood, feelings of guilt and worthlessness, feelings of helplessness and hopelessness, loss of appetite, sleep disturbance, psychomotor retardation) which have been used in previously validated scales of depression (Radloff, 1977). Items are rated on a 4-point scale (i.e., 0 to three) weighted by frequency of occurrence during the past week (i.e., responses ranging from rarely/none of the time – less than one day, to most/all of the time – five to seven days). Items 4, 8, 12, and 16 are reverse scored. Total scores range from 0 to 60 and are calculated by summing the individual item scores, with higher scores indicating more depressive symptomatology. Cut off scores are as follows: scores ranging from 15 to 21 indicate mild to moderate depression, and scores greater than 21 suggest the possibility of major depression. The CES-D has demonstrated high internal consistency across studies ($\alpha = .63$ to .91; Devins, Orme, & Costello, 1988; Radloff, 1977) and moderate test-retest reliability after a 3 month delay ($r = .61$) across diverse adult populations (Devins et al., 1988). In addition, the CES-D has demonstrated moderate correlations with the Hamilton Clinician’s Rating scale (Hamilton, 1960) and
with the Raskin Rating scale (Raskin, Schulterbrandt, Reatig, & McKeon, 1969) \((r = .44\) to .54) among a patient sample which suggests moderate criterion validity (Radloff, 1977). Cronbach's alpha coefficient was calculated for the overall sample indicating good reliability for the set of items on the CES-D \((\alpha = .91)\).

### 2.2.7 State Trait Anxiety Inventory for Adults – Form Y (Appendix J; STAI; Spielberger, Gorsuch, Lushene, Vagg, & Jacobs, 1983)

The STAI is a 40-item self-report questionnaire which measures both state (STAI-S; situational anxiety) and trait anxiety (STAI-T; dispositional anxiety). Each item is rated on a 4-point Likert scale (i.e., 1 to 4) with responses ranging from almost never/not at all to almost always/very much so. Total scores on each subscale (i.e., state and trait) range from 20 to 80 and are calculated by summing individual item scores. Higher scores are indicative of greater levels of anxiety. The STAI-T has been found to have good internal consistency \((\alpha = .89\) to .96) and have high test-retest reliability \((r = .65\) to .86; Speilberger et al., 1983). The STAI-S was found to have good internal consistency \((\alpha=.86\) to .95) and low to moderate test-retest reliability \((r = .16\) to .62; Speilberger et al., 1983). Difference in test-retest reliability coefficients between the STAI-T and the STAI-S are to be expected given that trait anxiety reflects a more enduring personality construct, while state anxiety is expected to fluctuate as it is impacted by temporary situational influences. Cronbach's alpha coefficients were calculated for the sets of items on the STAI-S and STAI-T indicating good reliability for the overall sample \((\alpha = .94\) and \(\alpha = .93\), respectively).

### 2.3 Procedure

Participants include male and female emerging adults obtained from the University of Regina, SIAST, and Adult Campus (Regina, Saskatchewan). Following
online consent, each participant was informed that upon completion of the study participants would receive either a 2% course credit for participation (University of Regina students) or participants would be entered into a draw to win a $50 Best Buy gift certificate (SIAST and Adult Campus students).

After provision of consent, participants completed a demographic form (5 minutes) and the self-report offending questionnaire (SRO-R; 20 minutes). The self-report offending questionnaire facilitated determination of participants that comprised the two groups: emerging adults with a history of offending (index, non-index, and status offenses), and emerging adults without a history of offending. To classify participants as an emerging adult with a history of offending, participants were required to have a history of an arrested or charged offense.

Following the completion of the initial demographic and self-report offending (SRO-R) forms, participants were asked to complete a number of questionnaires further assessing emerging adult psychological functioning (i.e., PAI [50 minutes], BEST [10 minutes], BSS [10 minutes], BIS-11 [10 minutes], CES-D [10 minutes], and STAI-Form Y [10 minutes]). BPD symptoms were assessed specifically by the first four questionnaires: (1) PAI (specific interest in the Borderline Features scale); (2) BEST (subscale A and B); (3) BSS; and (4) BIS-11. The CES-D and the STAI-Form Y were used to assess associated symptoms of depression and anxiety. Completion of the demographic form, self-reporting offending questionnaire, and the six measures of BPD features and associated psychopathology required approximately 2 hours. Upon completion of the on-line survey, participants were debriefed via a debriefing form (Appendix K).
3.0 Results

3.1 Descriptive Statistics

Two hundred and forty eight (n = 57 with a history of offending; n = 191 without a history of offending) emerging adults initially participated in this study. Of the 248 participants, 32 (six with a history of offending and 26 without a history of offending) did not complete the questionnaire battery and were therefore excluded from analysis rendering an attrition rate of 13%. In addition, 19 participants (six with a history of offending and 26 without a history of offending) were excluded from the analysis due to age exclusion criteria (i.e., participants must be between 18 to 26 years of age). Lastly, 10 participants (two with a history of offending and eight without a history of offending) were excluded from the study due to invalid PAI profiles. Prior to statistical analysis, outliers were identified. Statistical analysis was conducted with and without the outliers revealing no impact on the results; therefore the outliers were retained in the final analysis. The final sample size consisted of 187 participants (43 with a history of offending versus 144 without a history of offending) ranging from 18 to 26 years (32 males \(M_{\text{age}} = 20.47 \text{ years}, SD = 2.02\) and 155 females \(M_{\text{age}} = 20.08 \text{ years}, SD = 2.08\)). Participants were predominantly Caucasian (83.4%). Participants’ highest level of education was first year of university (42.8%), followed by second year of university (27.3%), third year of university (18.7%), fourth year of university (6.4%), more than four years of university (2.7%), and finishing high school (2.1%). Participants’ current relationship status included single (46.5%), dating (47.1%), common law/cohabiting/married (5.9%), and separated (0.5%). A large portion (i.e., 61.5%) of participants were employed part-time while attending school. Approximately 1/3 of
participants were strictly students. Participants current household income was dispersed as follows: 27.3% was less than $30,000; 12.3% ranged from $30,000 to $49,000; 31% ranged from $50,000 to $99,000; 27.3% ranged from $100,000 to $499,000; and 2.1% were greater than $500,000. Over half (i.e., 64.2%) of the participants’ current living arrangements were with one or both parents or extended family. Other living arrangements included living alone/with roommates/sibling/on residence (29.4%), living with spouse/partner or spouse/partner and child (5.3%), and living with children (1.1%). Parents’ relationship status was divided into two categories: (1) married/common law and (2) other (i.e., divorced, single, widowed, never together). The majority of participant’s parent’s relationship status was married/common law (71.7%). For descriptive information by sex within the overall sample, refer to Table 1.

Descriptive information was also collected for participants’ self-reported history of abuse (i.e., emotional, physical, sexual abuse). Approximately 1/3 of the participants reported some type of abuse: 29.4% reportedly experienced emotional abuse, 11.8% experienced physical abuse, and 12.3% experienced sexual abuse. See Table 2 for descriptive information on abuse history by sex for the overall sample.

For the purposes of the current study, participants were divided into two groups, those emerging adults with a history of offending ($n = 43; M_{age} = 20.95$ years, $SD = 2.34$, range = 18 - 26 years) and those without a history of offending ($n = 144; M_{age} = 19.91$ years, $SD = 1.92$, range = ages 18 - 26 years) as identified via an offending questionnaire (see Appendix D) based on a self-reported history of an arrested or charged criminal offense (see Tables 3 and 4 for descriptive information for groups).

Independent sample t-tests and chi-square analysis were conducted to examine

between group differences in regards to demographic information, however certain variables (i.e., school, current living arrangements) were excluded from chi-square analyses due to small sample sizes across the categories within the variable, too many categories comprising a variable (i.e., categories could not be collapsed into two or three categories), and the analyses were not relevant to the purposes of the current study.

Independent sample t-tests detected a statistically significant difference between groups in terms of age, \( t(185) = 2.65, p = .01, r = .19 \). Specifically, the group with a history of offending were significantly older \( (M_{\text{age}} = 20.95, SD = 2.34) \) than the group without a history of offending \( (M_{\text{age}} = 19.91, SD = 1.92) \). Although the difference in age is statistically significant, the difference may not be clinically meaningful. Further, this finding may be a function of the narrow age range included in the study (i.e., 18 to 26 years of age). In addition, the effect size for the mean age difference between the two groups is small (i.e., \( r = .19 \)) as the benchmarks for effect size using \( r \) are: .10 is a small effect, .30 is a medium effect, and .50 is a large effect (Field, 2009). Certain categorical demographic variables with more than three categories were collapsed into two categories in order to examine between group differences through chi-square analyses. Table 3 (page 60-61) indicates not applicable in the chi-square outcome column for these variables (as well as the variables excluded from the analysis) as the analysis did not include all the categories listed, rather condensed categories were utilized to run the analysis. Specifically, current household income was collapsed into two categories (i.e., less than $30,000 versus greater than $30,000). There was a statistically significant association between history of offending (history versus no history of offending) and current household income, \( \chi^2(1) = 13.92, p = .001 \). Based on the odds ratio, the odds of
having a household income of less than $30,000 were 3.63 times higher if the participants had a history of offending than if they did not have a history of offending. Ethnicity was collapsed into two categories (i.e., Caucasian versus other). There was no statistically significant association between ethnicity and history of offending (i.e., history versus no history of offending), \( \chi^2(1) = 0.77, p = .382 \). Level of education was collapsed into two categories (i.e., first year of post-secondary education or less versus more than one year of post-secondary education). There was no statistically significant association between level of education and history of offending (i.e., history versus no history of offending), \( \chi^2(1) = 0.06, p = .811 \). Lastly, relationship status was collapsed into two categories (i.e., single versus in some type of a relationship/dating). There was no statistically significant association between history of offending (i.e., history versus no history of offending) and relationship status, \( \chi^2(1) = 2.174, p = .140 \).

With respect to abuse history, chi-square analysis detected a statistically significant association between history of offending (history versus no history of offending) and abuse history (history of at least one type of abuse versus no history of any type of abuse), \( \chi^2(1) = 9.95, p = .002 \) (see Table 4; page 62). Based on the odds ratio, the odds of having a history of abuse were 3.03 times higher if the participants had a history of offending than if they did not have a history of offending. In addition, there was a statistically significant difference between those with a history of offending and those without in terms of the age the abuse occurred, \( t(42) = 2.29, p = .027, r = .33 \). Specifically, participants with a history of offending experienced abuse at an older age (\( M_{age} = 13.71 \) years, \( SD = 5.07 \)) than participants without a history of offending (\( M_{age} = \))
10.26 years, $SD = 4.71$). There was no statistically significant difference regarding the number of years the abuse was experienced.

Descriptive statistics were also computed for the group with a history of offending in terms of criminal variables. The group with a history of offending was comprised of 7 males ($M_{age} = 22.14$ years, $SD = 2.04$) and 36 females ($M_{age} = 20.72$ years, $SD = 2.37$; range = 18 – 26 years). Participants with a history of offending reported a mean age of 15.90 years ($SD = 2.69$; range = 18 – 26 years) for first contact with the police. Mean number of arrests was 2.12 ($SD = 2.13$; range = 1-13). The mean number of years since participants with a history of offending committed their most recent offence was 3.69 years ($SD = 2.72$; range = 0-13 years). Twenty-five percent of participants’ most recent offense was in the last year. For a detailed description of self-reported arrest and/or charge history see Table 5.

The most serious offense committed by each participant was also examined. This variable was created by reviewing the Criminal Code of Canada and the documents description of summary convictions and indictable offenses. Frequency of most serious offenses include property offense (41.9%), violent offense (18.6%), status offense (16.3%), public disorder (11.6%), traffic offense (7.0%), and liquor law violation (2.3%). For a comprehensive list of all the criminal offenses arrested or charged for within the history of offending group see Table 6.

3.1.1 BPD Features. Overall means were computed for the PAI-BOR and associated subscales (see Table 7): Mean T-scores on the PAI-BOR, BOR-A, BOR-I, BOR-N, and BOR-S range from 51.22 to 57.06. Scale elevations (i.e., T-score $\geq 70$) on the PAI-BOR scale and associated subscales (i.e., BOR-A, BOR-I, BOR-N, and BOR-S)

Note. PAI = Personality Assessment Inventory; PAI-SOM = Somatic Complaints Scale; SOM-C = Conversion Subscale of the PAI-SOM; SOM-S = Somatization Subscale of the PAI-SOM; SOM-H = Health Concerns Subscale of the PAI-SOM; PAI-ANX = Anxiety Scale; ANX-C = Cognitive Subscale of the PAI-ANX; ANX-A = Affective Subscale of the PAI-ANX; PAI-ARD = Anxiety-Related Disorders Scale; ARD-O = Obsessive-Compulsive Subscale of the PAI-ARD; ARD-P = Phobias Subscale of the PAI-ARD; ARD-T = Traumatic Stress Subscale of the PAI-ARD; PAI-DEP = Depression Scale; DEP-C = Cognitive Subscale of the PAI-DEP; DEP-P = Physiological Subscale of the PAI-DEP; PAI-MAN = Mania Scale; MAN-A = Activity Level Subscale of the PAI-MAN; MAN-G = Grandiosity Subscale of the PAI-MAN; MAN-I = Irritability Subscale of the PAI-MAN; PAI-PAR = Paranoia Scale; PAR-H = Hypervigilance Subscale of the PAI-PAR; PAR-P = Persecution Subscale of the PAI-PAR; PAR-R = Resentment Subscale of the PAI-PAR; PAI-SUI = Suicidal Ideation Scale; PAI-STR = Stress Scale.

η² = eta-squared. Eta-squared is a measure of effect size. The benchmarks for eta-squared include: .01 is a small effect size; .06 is a medium effect size, and .14 is a large effect size (Cohen, 1988).

*p < .05. ** p < .01. ***p < .001.

n = 43. b n = 144. c n = 187.
were examined to assess the presence of BPD features across the two groups. A T-score greater than or equal to 70 on the PAI scales suggests the prominence of the disorder, however, a diagnosis should not be made based solely on responses from this measure. The aforementioned scales were re-coded into high (clinically significant = T-score ≥ 70) and low (below threshold = T-score < 70) features based on T-score cut-off criteria. Accordingly, 11.8% (n = 22) of the entire sample demonstrated high BPD features on the PAI-BOR. Approximately 21% (n = 9) of participants with a history of offending reported high (clinically significant) BPD features compared to 9% (n = 13) of participants without a history of offending on the PAI-BOR (see Table 8 for frequency counts across groups).

Overall means were computed for the BEST subscales A (M = 14.16, SD = 5.65) and B (M = 5.66, SD = 2.24) (see Table 9). Item responses on the BEST subscales A and B were also examined. The eight items of the BEST A and the four items of the BEST B inquire about the nine criteria for BPD outlined in the DSM-IV-TR (APA, 2000) within a dimensional model. See Table 10 for frequency of items endorsed on the BEST A and B across groups, with attention to responses indicative of severe or extreme symptom presentation.

3.1.2 Associated BPD Symptomatology and Psychopathology. Levels of symptoms associated with BPD (i.e., impulsivity [BIS-11], suicidality [BSS], depression [CES-D], state and trait anxiety [STAI], remaining PAI clinical scales, and relevant PAI treatment scales) were examined across the entire sample and between the two groups (see Tables 7 and 9). Descriptive information for associated BPD symptomatology and psychopathology will be discussed below and followed by examination across groups.

**Note.** BEST (Pfohl & Blum, 1997). BEST = Borderline Evaluation of Severity Over Time; Subscale A = Negative Thoughts and Feelings; Subscale B = Negative Behaviours. 
\(a_n = 43\). \(b_n = 144\). \(cN = 187\).
3.1.3 Impulsivity. Overall means were computed for the BIS-11 and subscales (see Table 9): Mean scores on the BIS-11 and subscales (i.e., Attention, Motor, Impulsivity, Motor Impulsivity, Nonplanning Impulsiveness) ranged from 4.90 to 58.62. The BIS-11 total score was re-coded into high impulsiveness (Total score ≥ 72) and below threshold for high impulsiveness (Total score < 72). Below threshold for high impulsiveness should not necessarily be interpreted as low impulsiveness, rather participant scores did not reach the threshold for high impulsiveness. Among the entire sample, 9.6% (n = 18) demonstrated high impulsiveness. Across groups, 14.0% (n = 6) Self-Control, Cognitive Complexity, Perseverance, Cognitive Instability, Attentional of participants with a history of offending and 8.3% (n = 12) of participants without a history of offending obtained total scores indicative of high impulsivity.

3.1.4 Suicidality. BSS total score (M = 0.70, SD = 2.27) was re-coded into high suicidality (clinically significant = total score ≥ 24) and below threshold (total score < 24). Below threshold does not necessarily mean the absence of suicidality, rather lower levels or below clinical levels of suicidality. No participants demonstrated clinical levels of suicidal ideation. However, 4.8% (n = 9) of the entire sample (all females) reported a history of a suicide attempt on item 20 of the BSS. Of those with a history of a suicide attempt, 11.6% (n = 5) have a history of offending whereas 2.8% (n = 4) have no history of offending.

3.1.5 Depression. For the overall sample, the mean score for the CES-D was 11.97 (SD = 9.49; see Table 9; page 73). For descriptive purposes, the CES-D Total score was categorized as low depressive symptoms (i.e., none to very mild depressive symptoms; Total score = 0 to 14), mild to moderate depressive symptoms (Total score = 15 to 21),
and major depressive symptoms (Total score > 21) which may be indicative of major depression (see Table 11). Among the entire sample (N = 187) 15.0% demonstrated major depressive symptoms. More specifically, 20.9% of the group with a history of offending and 13.2% of the group without a history of offending endorsed items reflecting the presence of major depressive symptoms.

3.1.6 Anxiety. For the overall sample, mean scores were calculated for both state (\(M = 35.67, SD = 11.16\)) and trait (\(M = 38.04, SD = 10.57\)) anxiety (see Table 9; page 73). The group with a history of offending obtained a mean score of 39.02 (\(SD = 11.55\)) on state anxiety as compared to the group without a history of offending (\(M = 34.67, SD = 10.89\)). Participants in the group with a history of offending obtained a mean score of 40.14 (\(SD = 9.35\)) on trait anxiety as compared to the group without a history of offending (\(M = 37.41, SD = 10.86\)).

3.1.7 BPD associated psychopathology on the PAI Scales. For the overall sample descriptive statistics were computed for the remaining PAI clinical scales, three PAI treatment scales, and associated subscales. Mean T-scores range from 46.65 to 60.30. See Table 7 (page 69-70) for mean T-scores and Table 12 for frequencies of clinically significant T-scores on the aforementioned scales and subscales.

3.2 BPD Features as a Function of Group Membership

Hypothesis 1 stated that BPD features would be significantly more elevated in the group with a history of offending than the group without. To test this hypothesis, a series of between-group one-way ANOVAs were conducted for measures specifically examining BPD features (PAI-BOR and subscales, BEST A and B). Statistically significant differences between groups were observed across the PAI-BOR scale and

PAI-STR  2 (4.7)  4 (2.8)  N/A

Note. BPD = borderline personality disorder; PAI = Personality Assessment Inventory; PAI-SOM = Personality Assessment Inventory Somatic Complaints Scale; PAI-ANX = Personality Assessment Inventory Anxiety Scale; PAI-ARD = Personality Assessment Inventory Anxiety-Related Disorders Scale; PAI-DEP = Personality Assessment Inventory Depression Scale; PAI-MAN = Personality Assessment Inventory Mania Scale; PAI-PAR = Personality Assessment Inventory Paranoia Scale; PAI-SCZ = Personality Assessment Inventory Schizophrenia Scale; PAI-ALC = Personality Assessment Inventory Alcohol Problems Scale; PAI-DRG = Personality Assessment Inventory Drug Problems Scale; PAI-AGG = Personality Assessment Inventory Aggression Scale; PAI-SUI = Personality Assessment Inventory Suicidal Ideation Scale.

Clinically significant T-scores suggest the presence of the disorder, however, is not suffice for a diagnosis.

\( ^a n = 43. \quad ^b n = 144. \)
associated subscales with the exception of one (see Table 7; 69-70). Specifically, those with a history of offending had significantly higher levels of BPD features as compared to those without as measured by the PAI-BOR, $F(1, 185) = 8.11, p = .005, \eta^2 = .04$. Effect sizes ($\eta^2$) are determined based on the following benchmarks: small effect equals .01; medium effect equals .06; and a large effect is equivalent to .14 (Cohen, 1988). A small to medium effect size was observed on the PAI-BOR. Similarly, those with a history of offending had significantly higher levels of affect instability (BOR-A, $F(1, 185) = 4.46, p = .036, \eta^2 = .02$), negative relationships (BOR-N, $F(1, 185) = 8.23, p = .005, \eta^2 = .04$), and self-harm (BOR-S, $F(1, 185) = 6.42, p = .012, \eta^2 = .03$) than those without. Small effect sizes were observed for the BOR-A and BOR-S and a small to medium effect was observed for the BOR-N. No statistically significant difference was observed between groups with respect to identity disturbance.

Consistent with Hypothesis 1, there were statistically significant differences between groups on the BEST A, $F(1, 185) = 4.33, p = .039, \eta^2 = .02$, and BEST B, $F(1, 185) = 4.04, p = .046, \eta^2 = .02$, suggesting that those with a history of offending have significantly more negative thoughts and feelings (e.g., affect dysregulation, fears of abandonment, feelings of emptiness) and negative behaviours (e.g., impulsivity, inappropriate expressions of anger) symptomatic of BPD than those without a history of offending (see Table 9; page 73). Despite statistically significant outcomes, the effect size for the BEST A and B were small.

3.3 Associated BPD Symptomatology and Psychopathology as a Function of Group Membership
Hypothesis 2 stated that specific BPD symptomatology and associated psychopathology would be significantly more elevated in the group with a history of offending than in the group without as measured by the BIS-11 (i.e., impulsivity), BSS (suicidal ideation), CES-D (i.e., depression), STAI (i.e., state and trait anxiety), PAI clinical scales and subscales (i.e., somatic complaints, anxiety, anxiety-related disorders, depression, mania, paranoia, schizophrenia, antisocial features, alcohol problems, drug problems), and three specific PAI treatment scales and subscales (i.e., aggression, suicidal ideation, stress). To test this hypothesis, a series of between-group one-way ANOVAs were conducted for measures examining associated BPD symptomatology and psychopathology (i.e., BSS, BIS-11, CES-D, STAI-S, STAI-T, PAI clinical scales and subscales, specific PAI treatment scales). Results demonstrated mixed support for Hypothesis 2 (see Table 7 and 9; page 69-70, 73). Specifically, participants with a history of offending had significantly higher levels of impulsivity as measured by the BIS-11, $F(1, 185) = 7.74, p = .006, \eta^2 = .04$, than those without an offender history. A small to medium effect size was observed on the BIS-11. Similarly, the group with a history of offending had significantly higher levels of impulsivity on the following BIS-11 subscales: BIS Self-Control, $F(1, 185) = 5.82, p = .017, \eta^2 = .03$, BIS Cognitive Complexity, $F(1, 185) = 12.44, p = .001, \eta^2 = .06$, BIS Motor Impulsiveness, $F(1, 185) = 4.65, p = .032, \eta^2 = .03$, and BIS Nonplanning Impulsiveness, $F(1, 185) = 11.70, p = .001, \eta^2 = .06$, than those without an offender history. Observed effect sizes range from small to medium for the aforementioned subscales. No statistically significant differences were observed between groups on the remaining five BIS-11 subscales (i.e., Attention, Motor, Perseverance, Cognitive Instability, Attentional Impulsivity, see Table
Consistent with Hypothesis 2, there were statistically significant differences between groups in regards to situational anxiety (STAI-S), $F(1, 185) = 5.14, p = .025, \eta^2 = .03$, suggesting that the group with a history of offending have significantly more situational anxiety than the group without (see Table 9; page 73). The STAI-S demonstrated a small to medium effect size.

Statistically significant differences on the PAI scales provided further support for Hypothesis 2 (see Table 7 for complete list of the between-group comparisons for PAI scales and subscales; page 69-70). Results from the one-way ANOVA's for the PAI-BOR will not be reiterated in this section. Participants with a history of offending had significantly higher T-scores on 7 of the 13 remaining PAI clinical scales and specific treatment scales and 11 of 27 remaining PAI subscales than those without. Specifically, statistically significant differences were observed on the following PAI Scales: PAI-SOM, $F(1, 185) = 6.27, p = .013, \eta^2 = .18$; PAI-PAR, $F(1, 185) = 5.39, p = .021, \eta^2 = .17$; PAI-ANT, $F(1, 185) = 26.02, p < .001, \eta^2 = .35$; PAI-AGG, $F(1, 185) = 16.45, p < .001, \eta^2 = .29$; PAI-ALC, $F(1, 185) = 30.27, p < .001, \eta^2 = .38$; PAI-DRG, $F(1, 185) = 23.64, p < .001, \eta^2 = .34$; and PAI-STR, $F(1, 185) = 11.40, p = .001, \eta^2 = .24$. In addition, statistically significant between-group differences were demonstrated on the following PAI subscales: SOM Conversion subscale, $F(1, 185) = 6.47, p = .012, \eta^2 = .18$; SOM Somatization subscale, $F(1, 185) = 3.95, p = .048, \eta^2 = .14$; ARD Traumatic Stress subscale, $F(1, 185) = 5.40, p = .021, \eta^2 = .17$; DEP Physiological subscale, $F(1, 185) = 6.76, p = .010, \eta^2 = .19$; MAN Irritability subscale, $F(1, 185) = 3.88, p = .05, \eta^2 = 14$; PAR Persecution subscale, $F(1, 185) = 6.75, p = .01, \eta^2 = .19$; PAR Resentment subscale, $F(1, 185) = 8.07, p = .005, \eta^2 = .20$, ANT Antisocial Behaviours subscale, $F(1, 185) = 83$
66.41, \( p = .000, \eta^2 = .51 \); AGG Aggressive Attitude subscale, \( F(1, 185) = 13.29, p = .000, \eta^2 = .26 \); AGG Verbal Aggression subscale, \( F(1, 185) = 9.78, p = .002, \eta^2 = .22 \); and AGG Physical Aggression Subscale, \( F(1, 185) = 13.45, p = .000, \eta^2 = .26 \). Effect sizes (\( \eta^2 \)) are determined based on the following benchmarks: small effect equals .01; medium effect equals .06; and a large effect is equivalent to .14 (Cohen, 1988). In sum, the group with a history of offending demonstrated increased levels of psychopathology than the group without a history of offending.

In contrast, some of the current results were not supportive of Hypothesis 2 (see Table 7 and 9; page 69-70, 73). Specifically, there was no statistically significant difference between groups in terms of suicidality (BSS), trait anxiety (STAI-T), or depressive symptoms (CES-D). However, there was a trend toward those with an offender history having significantly more elevated levels of depression. Lastly, no statistically significant differences between groups were observed on the following PAI scales: Anxiety, Depression, Mania, Schizophrenia, and Suicidal Ideation. Overall, there was more psychopathology present in the group with a history of offending than the group without bolstering support for Hypothesis 2.

Hypothesis 3 stated that the group with an offender history would have scores in the clinical range for specific BPD associated psychopathology as measured by relevant PAI clinical scales (i.e., drug problems, alcohol problems, anxiety, depression, paranoia) and two of the PAI treatment scales (i.e., aggression, suicidal tendencies). To test this hypothesis, descriptive statistics were computed (i.e., frequencies) to examine the distribution of clinically significant T-scores for the PAI clinical scales and three treatment scales across groups with and without a history of offending (see Table 12;...
Specifically, each of the PAI scales were re-coded into high (clinically significant = T-score ≥ 70) and low (below threshold = T-score < 70) features based on T-score cut-off criteria. With respect to those with a history of offending, the PAI scales with the five highest percentages of elevations (T ≥ 70) include: Alcohol Problems (27.9%), Antisocial Features (25.6%), Borderline Features (20.9%), Drug Problems (18.6%), and Anxiety (18.6%). In addition, on the Antisocial Features scale, the subscale Antisocial Behaviours had a high percentage of elevations (41.9%). On the Borderline Features scale, the Negative Relationships subscale demonstrated a high percentage of elevations (20.9%). On the Anxiety scale, the Affective subscale had a high percentage of elevations (18.6%). On the Anxiety Related scale, the Traumatic Stress subscale demonstrated a high percentage of elevations (18.6%). Lastly, on the Paranoia scale, the Hypervigilance subscale had a high percentage of elevations (18.6%). On average, the group with a history of offending demonstrated clinical levels of BPD symptomatology and psychopathology more frequently than the group without history of offending demonstrating support for Hypothesis 3.

3.4 Association Between BPD Features and History of Abuse in the Group with a History of Offending

Hypothesis 4 stated that BPD features would be associated with an increased history of abuse (i.e., emotional, physical, sexual) in the group with a history of offending. To test this hypothesis, a chi-square analysis was conducted to examine the association between level of Borderline Features on the PAI- BOR (clinical level [T-score ≥ 70] versus below threshold [T-score < 70]) and abuse history (history of at least one type of abuse versus no history of any type of abuse). No statistically significant
association was observed between level of Borderline Features on the PAI-BOR and abuse history, \( x^2 (1) = 1.10, p = .295 \). The results suggest similar abuse experience across those with high and low BPD features among those with a history of offending.

### 3.5 Association Between BPD Features and Criminal Offense Variables in the Group with a History of Offending

Hypothesis 5 stated that BPD features would be associated with a greater number of offenses in the group with a history of offending. To test this hypothesis, an independent sample t-test was conducted to examine differences between those with clinical (T-score \( \geq 70 \)) and below threshold (T-score < 70) levels of BPD features and number of arrested/charged offenses. No statistically significant differences were observed for number of arrests/charges, \( t(41) = 0.36, p = .723 \). Further, no statistically significant differences were observed across related variables of age of first police contact, \( t(41) = 0.57, p = .570 \), and years since most recent offense, \( t(41) = 0.75, p = .458 \) (see Table 13).

Chi-square analysis was also conducted to examine within-group differences among those with a history of offending in terms of types of offenses. Specifically types of offenses were compared based on high and low BPD features as measured by the PAI-BOR in the group with a history of offending. A total of 42 participants within the group with a history of offending reported the types of offenses they had been arrested or charged for. One participant within the history of offending group reported having spent time in a correctional facility but did not indicate the type of offense committed. Based on the 42 participants' reports, a variable was created for the most serious offense committed by each participant as some participants reported multiple offenses. This

</tbody>
</table>

Note. BPD = borderline personality disorder; PAI-BOR = Personality Assessment Inventory Borderline Features Scale; high BPD features = T-score > 70 on the PAI-BOR; Low BPD Features = T-score < 70 on the PAI-BOR. Low BPD features does not mean there are no BPD features present rather the features did not reach clinical significance. Most serious offense refers to the most serious offense each individual with a history of offending were arrested or charged for. Status offense refers to drinking below the legal age limit and possession of alcohol under the legal age limit. Violent offense includes assault, sexual assault, impaired driving, and threats. Property offense included both offenses against rights of property and willful fraud and forbidden acts in respect of certain property (e.g., arson, armed robbery, theft, break and enter, drug trafficking, mischief). Traffic offense included driving with a suspended license, speeding, and other driving violations. Public Order included fighting in public and public disorder. Liquor Law violation included open alcohol within in a vehicle; status offenses were separated from this category.

a n = 9, b n = 34.
variable was created by referencing the Criminal Code of Canada’s divisions of offenses (i.e., summary offenses, indictable offenses). Chi-square analysis examined the association between high and low BPD features and types of offenses categorized based on the most serious offense committed by each individual (i.e., status offense, violent offense, property offense, traffic offense, public order, and liquor law violations) among the group with a history of offending. No statistically significant association between level of borderline features on the PAI-BOR (clinical level versus below threshold) and type of offense was observed, $x^2 (5) = 4.27, p = .511$ (see Table 13).

3.6 Sex Differences in BPD Features in the Group with a History of Offending

Hypothesis 6 stated that sex differences would be found among the group with a history of offending; specifically, we expected to find significantly higher BPD features among females with a history of offending as compared to males with a history of offending as measured by the BEST subscales (i.e., affect, negative behaviours), and PAI-BOR scale and subscales. To test this hypothesis, a series of independent t-tests were conducted. There were statistically significant differences across sex for all measures of BPD features (i.e., PAI-BOR, BOR-A, BOR-I, BOR-N, BEST A, BEST B) with the exception of the BOR-S. See Table 14 for comparison of BPD features across sex. These results are consistent with the literature as females present with BPD features more frequently than males (APA, 2000).

3.7 Predictors of History of Offending

Hypothesis 7 stated that BPD features would be predictive of group membership. To test this hypothesis, it was important to select one measure of BPD features to use in subsequent analyses. In order to do so, Pearson correlations were computed across the

following BPD specific scales and subscales: PAI-BOR, BOR-A, BOR-I, BOR-N, BOR-S, BEST A, BEST B. Statistically significant associations were observed across all measures (see Table 15). Given the statistically significant correlations across BPD specific measures and the wide use of the PAI-BOR in existing research, PAI-BOR was selected as the variable to be used in subsequent analyses (i.e., as a predictor in regression analyses). Further, Pearson correlations were computed to assess association between PAI-BOR across measures of associated BPD symptomatology and psychopathology (i.e., BSS, BIS-11, CES-D, STAI-S, STAI-T, and PAI scales). Lastly, Pearson correlations were computed to assess the association between PAI-BOR and other associated PAI scales. Statistically significant associations were observed between all measures at the $p < .01$ level with the exception of the one correlation between PAI-ALC and PAI-SUI which was significant at the $p < .05$ level (see Tables 16 and 17).

Binary logistic regression (hierarchical method) was conducted to determine if BPD features could predict group membership (i.e., history of offending versus no history of offending). PAI-BOR was selected as the BPD features measure to be used as the predictor in the following regression analysis. The first step was a test of a model with PAI-BOR as the one predictor variable. The model was statistically significant, $x^2 (1, N = 187) = 7.54, p = .006$, indicating that PAI-BOR reliably distinguishes group membership. The variance in group membership accounted for is small, however, with Nagelkerke $R^2 = .06$. The percentage of correctly classified cases overall decreased from 77% to 75.9%. Although the regression equation correctly classified 98.6% of the participants without a history of offending, 0% of the participants with a history of offending were correctly classified. See Table 18 for regression coefficients, Wald statistics, odds ratios,

94
and 95% confidence intervals for odds ratios for PAI-BOR as the predictor of group membership. The odds ratio suggests that participants are 1.04 times more likely to have a history of offending if they have BPD features. However, the odds ratio of 1.04 with a base rate of 1.0 demonstrates minimal change in the likelihood of having a history of offending on the basis of a one unit change in BPD features.

The existing literature identifies abuse history (e.g., Fagan, 2005; Kakar, 1996; Maxfield & Widom, 1996; Smith & Thornberry, 1995) and substance abuse (i.e., drug and alcohol problems; Bennett, Holloway, & Farrington, 2008; BJS, 1998) as risk factors associated with offending. The second step of the hierarchical logistic regression was a test of the full model which included four predictors of group membership: BPD features (PAI-BOR), abuse history (i.e., history of some type of abuse versus no history of abuse), drug problems (PAI-DRG), and alcohol problems (PAI-ALC). The second step was statistically significant, $\chi^2 (4, N = 187) = 35.80, p < .001$, indicating that the predictors reliably distinguish between those with and without a history of offending (see Table 18). The variance in group membership accounted for is moderate, with Nagelkerke $R^2 = .26$.

The increment in chi-square statistics after abuse history, drug problems, and alcohol problems were added in the second step of the model was statistically significant, $\Delta \chi^2(3) = 28.25, p < .001$, demonstrating an improvement in the model. The percentage of correctly classified cases overall improved to 80.2%. Specifically, the regression equation correctly classified 94.4% of the group without a history of offending and 32.6% of the group with a history of offending. Although the model improved when abuse history, PAI-DRG, and PAI-ALC were included with PAI-BOR as predictors of group membership, PAI-BOR was no longer a statistically significant predictor of group
membership. The odds ratios suggest that participants are 2.66 times more likely to have a history of offending if they have a history of abuse, 1.05 times more likely to have a history of offending if they have drug problems, and 1.06 times more likely if they have alcohol problems. In contrast, the odds ratio for PAI-BOR as a predictor in the full model suggests that participants are slightly less likely (OR = .98) to have a history of offending if they have BPD features. Based on the hierarchical logistic regression it appears the relationship between BPD features and group membership may be mediated by history of abuse, drug problems, and/or alcohol problems. In order to determine whether the relationship between BPD features (i.e., PAI-BOR) and history of offending is mediated by the aforementioned variables, it is necessary to complete a mediation analysis.

A mediator is defined as a variable that accounts for the relationship between the predictor variable and the outcome variable (Baron & Kenny, 1986). The Baron and Kenny (1986) method is the most common and frequently cited procedure for mediation analysis in psychological research (Preacher & Hayes, 2004). Despite its broad usage, the procedures outlined by Baron and Kenny (1986) fail to include formal testing of significance of the indirect effect in the outlined criteria for mediation analysis. Preacher and Hayes (2004) outline the importance of formal testing of statistical significance for indirect effects to avoid Type I and Type II error. Formal testing of statistical significance for indirect effects is a more direct method of hypothesis testing than the method outlined by Baron and Kenny (1986) leading to an increase in statistical power. Research suggests that the Baron and Kenny (1986) method demonstrates low statistical power in many situations (MacKinnon, Lockwood, Hoffman, West, & Sheets, 2002).
Preacher and Hayes (2004) developed a SPSS macro that formally tests the statistical significance of the indirect effect both parametrically (Sobel test) and nonparametrically (bootstrapping procedure) while concurrently providing the output required to assess mediation with the Baron and Kenny (1986) criteria.

Utilizing Baron and Kenny's criteria, the results indicated that the total effect of BPD Features, as measured by the PAI-BOR \( (B = .04) \) on history of offending (with or without a history of offending) was statistically significant \( (p = .01) \). This finding suggested that there is a greater elevation of BPD features among those with a history of offending than those without a history of offending (see Figure 1). The effect of BPD features \( (B = .01) \) on history of abuse (history of at least one type of abuse versus no history of any type of abuse) (i.e., mediating variable) was also statistically significant \( (p < .001) \) (see Figure 2). Specifically, there is a greater elevation of BPD features among those with a history of abuse than those without a history of abuse. The effect of abuse history \( (B = .90) \) on history of offending, when controlling for BPD features, was also statistically significant \( (p < .05) \). The latter suggested that participants with a history of abuse were more likely to have a history of offending than those without a history of abuse while controlling for BPD features. Lastly, the direct effect of BPD features \( (B = .03) \) on history of offending, when controlling for history of abuse, was not statistically different from zero \( (p = .052) \). The results demonstrate that after controlling for history of abuse, there is no statistically significant relationship between BPD features and history of offending, albeit there was a trend towards significance. Baron and Kenny's criteria for mediation were established. Our results suggest that history of abuse mediated the effect of BPD features on history of offending. There was also the potential
Figure 1. Direct effect of borderline features on history of offending

\[ c = .04^{**} \]

*Figure 1.* Direct effect of borderline features on history of offending

\[ **p < .01. \]
Figure 2. Borderline features affecting history of offending indirectly through abuse history.

*p < .05. ***p < .001.
for BPD features to be the mediator in the relationship between abuse history and history of offending as abuse history has been observed as a potential etiological correlate in the development of BPD features in the extant literature. Given the potential alternate relationship (BPD features as the mediating variable), mediation analysis was completed examining BPD features as a potential mediator in the relationship between abuse history and offending. The results did not support BPD features as a mediator in the relationship between abuse history and offending.

Sobel’s test (Sobel, 1982) is a parametric approach that formally measures the indirect effect through examination of the total effect. Specifically, Sobel’s test was also used to assess whether or not the difference between the total effect and the direct effect (addition of the mediator) of BPD features on history of offending is statistically significant. Results of the Sobel test were consistent with the Baron and Kenny approach suggesting that abuse history mediates the relationship between BPD features and history of offending, $z = 2.06, p < .05$. Although Sobel’s test is superior to the Baren and Kenny (1986) method in terms of statistical power (see MacKinnon et al., 2002), the Sobel test is problematic in the sense that it relies on a large sample size and assumes that the distribution of the indirect effect follows a normal distribution under the null hypothesis. It has been argued that the bootstrapping method is a more appropriate approach to formally measuring the size of the indirect effect as it does not assume that the distribution of the indirect effect is normal, therefore avoiding problems regarding power that are often introduced by asymmetries and other forms of non-normality in the sampling distribution of the indirect effect (Shrout & Bolger, 2002). Bootstrapping is a nonparametric approach to effect size estimation and hypothesis testing (Preacher &
Hayes, 2004). The bootstrapped estimate of the true indirect effect was estimated to lie between .0246 and .0015 with 95% confidence. Because zero is not in the 95% confidence interval, it can be concluded that the indirect effect is different from zero at \( p < .05 \) (two-tailed). Overall, the results of the three mediation analyses provide converging evidence that the association between borderline features and history of offending was fully mediated by history of abuse.

Although history of abuse significantly mediated the relationship between BPD features and history of offending, logistic regression suggested that drug problems and alcohol problems may also be statistically significant mediators in the relationship. Utilizing Baron and Kenny’s criteria, the results indicated that that the total effect of BPD Features, as measured by the PAI-BOR \( (B = .04) \) on history of offending (with or without a history of offending) was statistically significant from zero \( (p = .01) \). This finding suggested that there is a greater elevation of BPD features among those with a history of offending than those without a history of offending (see Figure 1). The effect of BPD features \( (B = .46) \) on drug problems (PAI-DRG; mediating variable) was also statistically significant \( (p < .001) \) (see Figure 3). Specifically, there is a greater elevation of BPD features among those with higher levels of drug problems than those with lower levels or no drug problems. The effect of drug problems \( (B = .06) \) on history of offending, when controlling for BPD features, was also statistically significant \( (p < .01) \). The latter result suggested that participants with a high level of drug problems were more likely to have a history of offending while controlling for BPD features. Lastly, the direct effect of BPD features \( (B = .01) \) on history of offending, when controlling for drug problems, was not statistically different \( (p = .52) \). The results demonstrate that after controlling for drug problems and history of offending, the relationship between BPD features and history of offending is fully mediated by history of abuse.
Figure 3. Borderline features affecting history of offending indirectly through drug problems.

***p < .001.
problems, there is no relationship between BPD features and history of offending. Given that all of Baron and Kenny’s criteria for mediation were established, the present findings suggest that drug problems mediated the effect of BPD features on history of offending.

Results of the Sobel test were consistent with the Baron and Kenny approach and suggested that the relationship between BPD features and history of offending is mediated by drug problems, $z = 2.94, p < .01$. Lastly, the bootstrapped estimate of the true indirect effect was estimated to lie between 0.0560 and 0.0103 with 95% confidence. Because zero is not in the 95% confidence interval, it can be concluded that the indirect effect is different from zero at $p < .05$ (two-tailed). Overall, the results of the three mediation analyses provide converging evidence that the relationship between borderline features and history of offending was mediated by drug problems.

Based on results from the logistic regression, alcohol problems was tested as a mediator in the relationship between BPD features and history of offending. Once more, utilizing Baron and Kenny’s criteria, the results indicated that the total effect of BPD Features, as measured by the PAI-BOR ($B = .04$) on history of offending (with or without a history of offending) was statistically significant ($p < .01$). This finding suggested that there is a greater elevation of BPD features among those with a history of offending than those without a history of offending (see Figure 1). The effect of BPD features ($B = .50$) on alcohol problems (PAI-ALC; mediating variable) was also statistically significant ($p < .001$) (see Figure 4). Specifically, there is a greater elevation of BPD features among those with higher levels of alcohol problems than those with lower levels or no alcohol problems. The effect of alcohol problems ($B = .07$) on history of offending, when controlling for BPD features, was also statistically significant ($p < .001$). The latter
Figure 4. Borderline features affecting history of offending indirectly through alcohol problems.

***p < .001.
finding suggested that participants with a high level of alcohol problems were more likely to have a history of offending, while controlling for BPD features. Lastly, the direct effect of BPD features \( (B = .01) \) on history of offending, when controlling for alcohol problems, was not statistically significant \( (p = .72) \). The results demonstrate that after controlling for alcohol problems, there is no relationship between BPD features and history of offending. Given that all of Baron and Kenny's criteria for mediation were established, the present findings suggested that alcohol problems mediated the effect of BPD features on history of offending.

Results of the Sobel test were consistent with the Baron and Kenny strategy and suggesting that the relationship between BPD features and history of offending is mediated by alcohol problems, \( z = 3.43; p < .001 \). Lastly, the bootstrapped estimate of the true indirect effect was estimated to lie between .0620 and -.0170 with 95% confidence. Because zero is not in the 95% confidence interval, it can be concluded that the indirect effect is different from zero at \( p <.05 \) (two-tailed). Overall, the results of the three mediation analyses provide converging evidence that the relationship between borderline features and history of offending was fully mediated by alcohol problems. In sum, mediation analysis suggests that abuse history, drug problems, and alcohol problems are all statistically significant mediators in the relationship between BPD features and history of offending.
4.0 Discussion

The purposes of the current study were fourfold: (1) assess for BPD features dimensionally using multiple valid measures among a heterogeneous male and female emerging adult sample with and without a history of offending; (2) compare BPD features and associated psychopathology across both emerging adults with and without a history of offending; (3) explore the relationship between BPD features, abuse history, type/number of offenses, and demographic information in the group with an offender history; and (4) examine potential predictors (i.e., BPD features) of offender status. In order to address the above, a demographic form and multiple measures designed to assess for BPD features, associated BPD symptomatology and psychopathology were administered to a sample of 187 emerging adults (43 with a history of offending and 144 without a history of offending). Group membership (i.e., group with a history of offending versus group without a history of offending) and criminal variables were established and evaluated based on a self-report offending questionnaire. Additional foci of the study included the evaluation of criminal variables and abuse history in relation to BPD features within the group with a history of offending. Lastly, potential predictors of offender status were examined in detail. Specific study findings and association with existing research are discussed in accordance with the order in which the purposes were previously itemized. Future directions and clinical implications will follow.

4.1 Prevalence of Clinical BPD Features

Overall, 11.8% of the full sample demonstrated clinical BPD features. The frequency of BPD features among undergraduate emerging adults (i.e., 11.8%) is similar to that found by Trull (1995). Trull examined the prevalence rate of BPD features among
a non-clinical college sample (N = 1697). Consistent with the current study, the PAI-BOR (Morey, 1991) was utilized as the estimate of BPD features. Approximately 15% of Trull's sample demonstrated clinical BPD features on the PAI-BOR. BPD prevalence rates identified by the current study and Trull are higher than rates of BPD in the general population (i.e., 2%-6%; APA, 2000; Grant et al., 2008), albeit the general population base rate focuses on a diagnosis rather than the presence of BPD features within a dimensional framework. Use of a dimensional framework is likely to lead to higher estimates of BPD as such a framework does not rely on the diagnostic criteria threshold outlined in the DSM-IV-TR (APA, 2000; 5/9 BPD symptoms present) to provide a BPD diagnosis. Rather, a dimensional framework focuses on the level or amount of features present.

A base rate of BPD features in an emerging adult population with a history of offending was established. Specifically, 20.9% of the emerging adults with a history of offending demonstrated clinical BPD features (T > 70) on the PAI-BOR Scale as compared to 9% of emerging adults without a history of offending. The current findings suggest that clinical levels of BPD features are more frequent (i.e., 20.9%) among emerging adults with a history of offending than those without, despite utilizing a non-incarcerated sample. Furthermore, 20.9% is similar to rates of self-reported clinical BPD features (i.e., 17%) demonstrated by Taylor et al. (2009) among incarcerated male adolescent/emerging adult offenders. The current study demonstrated a slightly higher prevalence rate of BPD and this finding may be the result of having a predominantly female sample (i.e., BPD features are more prevalent in females), and the inclusion of a slightly older age group (i.e., features become more pronounced). In comparison to
additional established base rates of BPD features/diagnosis among adolescent/emerging adult offenders (i.e., approximately 17% to 37%; Eppright et al., 1993; McManus et al., 1984; Taylor et al., 2009) and emerging adult/adult offenders (i.e., approximately 13% to 57%; Black et al., 2007; Blackburn & Coid, 1999; Davison et al., 2001; Dixon et al., 2008; Grella et al., 2008; Jordan et al., 1996; Logan & Blackburn, 2009; Stuart et al., 2006; Timmerman & Emmelkamp, 2005; Trestman et al., 2007; Warren et al., 2002; Zlotnick, 1999; Zlotnick et al., 2008) the base rate in the current study fell in the lower end of each of the established ranges, albeit the aforementioned ranges were found in incarcerated samples. The latter may be the result of utilizing a non-incarcerated group with a history of offending. Through examination of the BPD prevalence rate observed in the current study among emerging adults with a history of offending in comparison to existing studies on incarcerated samples it appears that emerging adults who are incarcerated may have more elevated BPD features than those with a history of offending. Further research would be required to verify this proposition.

It has been estimated that BPD comprises 10% to 25% of all inpatient psychiatric admissions (Bender et al., 2001; Springer & Silk, 1996; Widiger & Weissman, 1991) and 10 to 20% of outpatients (Korzekwa et al., 2008; Widiger & Weissman, 1991; Zimmerman & Mattia, 1999). The frequency of clinical BPD features (i.e., 20.9%) among emerging adults with a history of offending depicted in the current study is consistent with the prevalence rates of a BPD diagnosis in inpatient and outpatient clinical samples. In the current study BPD feature prevalence rates may have surpassed the estimates of BPD in clinical samples if a larger sample size had been obtained. Due to the difficulties in treating BPD, the severe interpersonal problems associated with the
disorder, and the extensive mental health resources utilized by this population, it is important to understand the prevalence of BPD features among those with a history of offending in both non-incarcerated (e.g., probation) and incarcerated settings. This knowledge may aid in decreasing recidivism rates and institutional infractions if appropriate prevention and intervention programs can be developed and implemented.

Multiple measures assessing BPD features (i.e., PAI and BEST) were utilized to assist in determining whether BPD features are increasingly elevated among emerging adults with a history of offending as compared to those without (e.g., BEST). The inclusion of multiple measures is an important strength of the current study relative to prior research. A total score on the BEST, however, is not included in this study as the total score requires scoring the BEST Subscale C which inquires about treatment adherence. Since a non-clinical sample was utilized for this study, BEST Subscale C was not included as many of the participants had not experienced any form of psychological/psychiatric treatment. As a result the BEST total score was not rendered which typically divides participants into those that are experiencing mild, moderate, or severe BPD symptoms. In place of the BEST total score, BEST Subscale A and B were the foci, both of which include items inquiring about the nine BPD symptom criteria outlined in the DSM-IV-TR (APA, 2000). This method allowed for comparisons on the presence of BPD symptoms but does not allow for an estimated prevalence rate of those with moderate to severe BPD features overall.

For the BEST subscales A and B base rates were established by identifying the extent to which each symptom caused distress across the two groups. Notable base rates were identified for the following BPD symptoms in terms of causing extreme distress:
fears of abandonment (14% with offender history versus 6.3% without); and feelings of emptiness (7% with offender history vs. 2.1% without). Notable base rates were further identified for the following BPD symptoms in terms of causing severe distress: instability in interpersonal relationships (14% with an offender history versus 6.3% without); emotional dysregulation (9.3% with an offender history versus 2.8% without); impulsivity (11.6% with an offender history vs. 2.8% without); and inappropriate expressions of anger (7% with an offender history vs. 2.1% without). Base rates for the aforementioned symptoms were observably higher for the group with an offender history than the group without an offender history.

4.2 Demographic Information and Abuse History Across Groups

Significant differences were observed between emerging adults with and without a history of offending in terms of demographic information and abuse history. Specifically, emerging adults with a history of offending tended to be slightly older (20.95 years vs. 19.91 years). Despite the difference in age, emerging adults with a history of offending were more likely than those without to have a current household income of less than $30,000 (i.e., low income). This is alarming when one considers that the mean family size in the group with an offender history is 3.81 ($SD = 1.65$) and that a household income of less than $30,000 among a four person family is below the poverty line in Saskatchewan (Canadian Council on Social Development, 2002). This result is consistent with the literature that has consistently demonstrated a link between low income families and crime (Kent, 2009). Specifically, the National Longitudinal Survey of Youth (Kent, 2009) demonstrated that 20% of adolescents from low income families are charged with an adult crime by the age of 24 (i.e., emerging adulthood) as compared
to 16% of adolescents from middle income and 12% of adolescents from high income families. In addition, 29% of adolescents from low income families failed to complete high school, and only 10% of emerging adults from low income families continued on to graduate from a four-year college, which may perpetuate a low income status for subsequent generations. Although the participants with a history of offending in the current study are undergraduates, they may not complete their program and therefore this trend cannot be disregarded. The results of the current study support the existing literature suggesting that low income may be a risk factor for criminal activity.

In addition, history of abuse varied between the two groups. In particular, emerging adults with a history of offending were more likely to have experienced some type of abuse (i.e., emotional, physical, sexual) than those without. In terms of base rates of self-reported types of abuse, emotional abuse was the most frequently reported type of abuse among emerging adults with an offender history (51.2%), followed by sexual abuse (20.9%), and physical abuse (18.6%). Approximately half of the group with an offender history reported experiencing some type of abuse compared to 1/4 of the group without an offender history. Similar rates were reported in Dietrich (2003) as over half of their emerging adult/adult sample of serious incarcerated offenders reported a history of some type of maltreatment. The cycle of violence theory proposes that victims of child maltreatment are at high risk of engaging in crime; the literature has demonstrated some support for this theory among adolescents/emerging adults and emerging adults/adults (e.g., Kakar, 1996; Smith & Thornberry, 1995; Maxfield & Widom, 1996).

Of note was the observed difference in the age the abuse occurred across groups; emerging adults with a history of offending experienced abuse at an older age than
emerging adults without a history of offending (13.71 years vs. 10.26 years). The results from the current study appear to suggest that abuse during adolescence may have a more significant impact on individuals in terms of the potential for criminal behaviour than abuse experienced at a younger age. Potential factors involved in this varied experience may include level of cognitive functioning; as adolescents may have an increased awareness and understanding of the unjust abuse they are experiencing and therefore may resort to engaging in different coping strategies or behaviours, albeit possibly negative (i.e., criminal behaviour). However, these findings may be a function of our sample size. Subsequent research with a larger sample size would be required to explore these speculations further.

4.3 Comparison of BPD Features Across Groups

The current study aimed to improve on the methodological limitations of past research on BPD and adolescent/emerging adult offenders (e.g., Taylor et al., 2009) by assessing for BPD features, associated BPD symptomatology, and psychopathology using multiple valid measures among a heterogeneous male and female emerging adult sample with and without a history of offending. Hypothesis 1 stated that BPD features would be significantly more elevated in the group with a history of offending than the group without. In sum, the results support this hypothesis. Two validated measures (PAI; Morey, 1991; BEST; Pfohl & Blum, 1997) that assess for BPD features specifically were utilized to test the aforementioned hypothesis, demonstrating consistent results, lending further support to this hypothesis. BPD features, specifically affect instability, negative relationships, and self-harm were more prominent in the group with a history of offending than the group without as measured by the PAI. Further, thoughts and feelings
characteristic of BPD (i.e., feelings of emptiness, intense fears of abandonment, emotional dysregulation), and negative behaviours characteristic of BPD (i.e., self-harm, impulsivity, inappropriate expressions of anger, paranoia, instability in interpersonal relationships) were more pronounced in the group with a history of offending than the group without as measured by the BEST.

One specific BPD feature was similar between emerging adults with and without a history of offending. Specifically, identity problems as measured by the Identity Problems subscale on the PAI Borderline Features scale, was not significantly different between groups. This finding may be a consequence of a small sample for the group with a history of offending. Alternatively, identity problems may be a feature of BPD that is less pronounced among emerging adults with a history of offending as compared to those without. Emerging adulthood has been described as a period of time in the life span where identity exploration and confusion is common (Arnett, 2007). Therefore, the lack of significant differences observed between emerging adults with and without a history of offending in terms of identity problems may be a function of the time period focused on within the current research. Specifically, we may expect to find similar rates of identity problems among emerging adults in general (i.e., with or without a history of offending). Differences in regards to this specific symptom may be more prominent among individuals with a history of offending in the adulthood period of the lifespan. To date, there is limited research specifically examining identity problems as a feature of BPD among adults with a history of offending. In one existing study Leichsenring, Kunst, and Hoyer (2003) examined the relationship between borderline personality organization (i.e., identity diffusion, primitive defense mechanisms, and reality testing) and antisocial
features, neuroticism, and interpersonal problems among a sample of incarcerated violent adult offenders (N = 91; Mean age = 34.90). Leichsengring et al. demonstrated a significant association across all variables of interest, suggesting that identity problems were experienced by incarcerated adults. Further research to delineate this relationship further is warranted.

This investigation is the first to examine BPD features, utilizing BPD specific measures, in a sample of emerging adults with an offender history with the inclusion of a comparison group (i.e., emerging adults without a history of offending). Therefore, these findings extend the adolescent/emerging adult offender and emerging adult/adult offender literature beyond estimated prevalence rates to demonstrate that individuals with a history of offending demonstrate more prominent BPD features than individuals without a history of offending. The inclusion of a comparison group facilitated the extension of this avenue of research. In particular, estimated base rates are limited in terms of generalizability across studies due to the inclusion of different measures, varied sample characteristics (e.g., incarcerated, newly incarcerated, history of offending, violent offenders), and different methods of assessment (i.e., dimensional versus diagnostic). Direct comparisons between samples allow us to make stronger conclusions about the association between BPD features and offender status. In turn, findings from such research are able to highlight areas of focus for the development and implementation of tailored assessment protocols and prevention, intervention, relapse prevention programs for incarcerated and non-incarcerated (i.e., probation) individuals.

4.4 Comparison of Associated BPD Symptomatology and Psychopathology Across Groups
Hypothesis 2 stated that specific BPD symptomatology and associated psychopathology would be significantly more elevated in the group with a history of offending than in the group without as measured by the BIS-11 (i.e., impulsivity), BSS (suicidal ideation), CES-D (i.e., depression), STAI (i.e., state and trait anxiety), remaining PAI clinical scales and subscales, and specific PAI treatment scales. The results of the current investigation demonstrate mixed support for Hypothesis 2. Specifically, participants with a history of offending had significantly higher levels of impulsivity than participants without a history offending. Elevated levels of impulsivity among those with a history of offending is consistent with the literature on incarcerated offenders (Krischer et al., 2007; Wilson et al., 2001) and those with a history of offending (Langhinrichsen-Rohling et al., 2004; Pfefferbaum & Wood, 1994). In the current study, higher levels of the following aspects of impulsivity (as measured by the BIS-11) were experienced by the group with an offender history: self-control (e.g., difficulties with planning and thinking carefully), cognitive complexity (e.g., does not enjoy challenging mental tasks), motor impulsiveness (e.g., acting out at the spur of the moment and demonstrating, inconsistent life-style), and nonplanning impulsiveness (e.g., difficulties with planning and thinking carefully, does not enjoy challenging mental tasks). These findings suggest that impulsivity, a specific BPD feature, may play a significant role in offending. The latter is consistent with the General Theory of Crime (GTC; Gottfredson and Hirschi, 1990) that proposes that poor self-control is the primary etiological factor in the development of criminal behaviour. However, the primary criticism of the GTC is that it is overly simplistic (i.e., other factors contribute to the likelihood of offending beyond poor self-control). Findings from the current study supported this criticism in
that additional risk factors (e.g., abuse history, low income, emotional dysregulation, self harm) were also associated with offending history.

Also, in support of Hypothesis 2, the group with a history of offending demonstrated higher elevations of state anxiety (i.e., situational) than those without a history of offending. The findings suggest that state anxiety is more prominent among individuals with a history of offending than those without. Anxiety disorders commonly co-occur among individuals with BPD (Zanarini et al., 2004; Zimmerman & Mattia, 1999). In addition, the rates of anxiety among emerging adult/adult offenders is high (23.9% to 43.6%; i.e., Grella et al., 2008; Trestman et al., 2007). The aforementioned literature did not focus on state and trait anxiety. The current study adds to the current literature in this regard as these specific forms of anxiety, as opposed to a specific anxiety disorder were examined. The current study demonstrates a specific form of anxiety that may be more prominent in individuals with a history of offending. These findings may be associated with the elevations in impulsivity observed in the group with a history of offending. Individuals with a history of offending may experience elevated state anxiety and, given co-existing poor self-control, may impulsively engage in unhelpful coping strategies or behaviours to alleviate the unpleasant feeling of anxiety (e.g., criminal behaviours).

Findings from the current study suggest that individuals with a history of offending may have increased difficulties with anxiety as a response to a situation as opposed to anxiety as a general personality characteristic. This appears consistent with the proposed, new criteria outlined for BPD in the DSM-V (i.e., anxiousness; APA, 2010). Anxiousness is described as intense feelings of nervousness, tenseness, or panic,
often in reaction to interpersonal stresses. Interpersonal stresses are very situation specific, therefore it is understandable that individuals with heightened BPD features (characterized by frequent interpersonal difficulties) may display a higher level of state anxiety. The aforementioned result has important clinical implications as it has the potential to inform assessment and intervention. Future research is required to further examine the various forms of anxiety experienced by offenders and the impact it has on their criminal behaviour.

Further, comparisons between groups on the remaining PAI clinical scales and subscales, and specific treatment scales demonstrated higher levels of paranoia (persecution and resentment), drug problems, alcohol problems, aggression (aggressive attitude, verbal aggression, physical aggression), posttraumatic stress (i.e., anxiety related), and physiological depressive symptoms, in terms of associated BPD symptomatology and psychopathology. The current findings are consistent with the offender literature, as paranoia (Krischer et al., 2007), substance problems (Bennett et al., 2008; BJS, 2006a; BJS, 2006b; Gunter et al., 2008; BJS, 1998; Peters et al., 1998; Stewart & Trupin, 2000), and inappropriate anger/aggression (Plattner et al., 2007; Wilson et al., 2001) have been observed among offenders.

In terms of posttraumatic stress, PTSD is common among emerging adults/adult offenders (11.4% to 28.6%; Grella et al., 2008; Trestman et al., 2007). The current study assessed for the presence of PTSD via the Traumatic Stress subscale of the PAI Anxiety Related Disorders (PAI-ARD) scale. This scale assesses the physiological symptoms of PTSD. Traumatic stress was the only anxiety related disorder subscale notably different between groups as measured by the PAI-ARD (versus PAI Obsessive-Compulsive and
Phobias Subscales). These findings suggest that the physical symptoms of PTSD are more pronounced among emerging adults with a history of offending than emerging adults without a history of offending. As mentioned above, posttraumatic stress is a common experience amongst offenders (e.g., Grella et al., 2008; Trestman et al., 2007) among the offender literature, and observed in the current sample. In addition PTSD co-occurs with BPD at high rates (35%; Zanarini et al., 2004). This controversy requires a brief discussion. To clarify, the greatest similarity between the two disorders relates to the presence of a trauma (e.g. abuse), which is required in order to be diagnosed with PTSD (APA, 2000). On the other hand, there is no such requirement for the diagnosis of BPD, albeit many patients with BPD present with histories of traumatic experiences. Recent arguments propose that individuals meeting criteria for BPD who have histories of trauma should be classified as having PTSD instead as it may be a more fitting diagnosis due to the presence of trauma (Fish, 2004; Herman, Perry, & Van der Kolk, 1989). Feminists have also critiqued the use of the BPD diagnostic label among those who have experienced childhood trauma (Becker, 2000; Fish, 2004, Shaw & Proctor, 2005). Fish (2004) refers to the diagnosis of BPD among previously abused women as a misdiagnosis, one that stigmatizes women by labeling them with a rather untreatable disorder (i.e., BPD) while more treatable posttraumatic conditions (e.g., PTSD) caused by trauma or situational stress go underdiagnosed in female populations. In sum, it is not surprising that traumatic stress was elevated among the sample with a history of offending, as this group also demonstrated elevations in BPD features, and a history of abuse. Despite the controversy, BPD remains its own diagnostic entity in the DSM-IV-
TR (APA, 2000), and will continue to be a listed personality disorder in the upcoming DSM-V (APA, 2010).

Additional differences between groups were identified when the remaining PAI clinical scales and specific treatment scales were examined. Emerging adults with a history of offending demonstrated increased elevations in regards to somatic complaints (i.e., conversion, somatization), antisocial features (i.e., antisocial behaviours), stress, and irritability (i.e., symptom of mania) than emerging adults without a history of offending. Elevations on antisocial features, specifically antisocial behaviours were expected among the group with a history of offending, as they have engaged in one or more ‘antisocial’ criminal behaviours. Elevations in stress among the group with a history of offending is understandable when one considers the presence of BPD features among this group. Individuals with BPD features tend to have poor coping skills and are likely to cope with stress in a less effective way than individuals without BPD features (Linehan, 1993) therefore exacerbating the stress experienced. The PAI Irritability subscale on the Mania Scale focuses on the presence of interpersonal difficulties resulting from an individual’s frustration with the inability or unwillingness of others to keep up with their plans, demands, or expectations (Morey, 1996). Although this symptom is classified under mania, it appears very similar to interpersonal instability often detected in individuals with high levels of BPD features or a BPD diagnosis. Interpersonal difficulties are likely present in the emerging adults group with a history of offending as these individuals have a tendency to act impulsively, and behave in antisocial ways. Lastly, elevations in somatic complaints in the group with a history of offending were observed, specifically in regards to conversion and somatization. Conversion symptoms refer to rare symptoms of
sensory or motor dysfunctions associated with conversion disorder. The Conversion subscale of the PAI Somatic Complaints scale can become elevated among chronic alcoholics who are beginning to suffer from neurological problems as a result of the alcohol abuse. Alcohol problems were elevated in the group with a history of offending so elevations on these two scales may be associated. Somatization refers to frequent experience of various common physical symptoms and complaints of ill health and fatigue (e.g., headaches, back problems, pain; Morey, 1996). Increased levels of somatization is noteworthy, particularly when one considers that the Physiological subscale on the PAI Depression scale was also elevated. Recent research has revealed a relationship between BPD features/diagnosis and perceptions of pain among chronic pain patients (Gooding, 2011). The prevalence of BPD in chronic pain populations is reported to range between 1-17% (Conrad et al., 2007; Fishbain, Goldberg, Meagher, Steele, & Rosomoff, 1986; Gatchel, Garofalo, Ellis, & Holt, 1996; Gooding, 2011; Kinney et al., 1993; Large, 1986; Polatin, Kinney, Gatchel, Lillo, & Mayer, 1993; Reich, Tupin & Abramowitz, 1983). Gooding (2011) demonstrated that BPD was associated with greater perceptions of pain intensity and interference of pain on daily activities, and lower perceived control over pain. Gooding (2011) attributes these findings to the poor coping skills present among individuals with BPD features.

In contrast to the above, some of the current results were not supportive of Hypothesis 2. Specifically, there was no significant difference between groups in terms of suicidal ideation (i.e., suicidal thoughts or ideas), trait anxiety (i.e., a general tendency or disposition to respond with an inappropriate level of anxiety to perceived threats in the environment), and depressive symptoms. However, there was a trend toward those with
an offender history having significantly more elevated levels of depressive symptoms (as measured by the CES-D). Major depression often co-occurs in individuals with BPD (Zanarini et al., 2004; Zimmerman & Mattia, 1999). In addition, major depression is prevalent among incarcerated offenders (i.e., 23% to 30%; BJS, 2006a; Grella et al., 2008; Gunter et al., 2008). A larger sample size for the group with a history of offending may have yielded significant differences in terms of the presence of depressive symptomatology. In addition, no significant differences were observed on the PAI Anxiety, Depression, Mania, Schizophrenia, and Suicidal Ideation scales.

The findings that there was no difference between groups in regards to suicidal ideation on the PAI Suicidal Ideation Scale, or on the BSS (as noted above) requires further discussion as there were significant differences between groups in regards to self-harm as indicated by the PAI Borderline Features Self-Harm subscale. This result was not expected as self-harm and suicidal ideation are both common among incarcerated offenders (Alessi et al., 1984; Bailey, 1996; Holley et al., 1995; Kenny et al., 2008). One may speculate that self-harm itself may be more consistent with the type of negative behaviours demonstrated by individuals with BPD than suicidal ideation. Individuals with BPD have difficulty regulating their emotions and as a result may self-harm to cope with negative emotions or feelings. It is possible that such individuals spend less time thinking about suicide as a function of impulsivity, low self-control, and difficulties regulating emotions and therefore are more likely to act rather than engage in extensive suicidal ideation. The findings from the current study lend further support to clarifying the differences across these two groups in this respect. First, self-harm is one of the criteria for BPD outlined in the DSM-IV-TR (APA, 2000) whereas suicidal ideation is
Furthermore, self-harm was observed as significantly different between the two study groups, even in a sample that has arguably high rates of self-harm behaviours (i.e., undergraduate samples; 12-38%; Briere & Gil, 1998; Pol, & Lis, 2009; Whitlock, Eckenrode, & Silverman, 2006). It is important to note that the current study yielded mean BSS scores (i.e., suicidal ideation; $M = 0.70$, $SD = 2.27$) consistent with existing research (e.g., $M = 0.77$, $SD = 2.55$; Van Orden et al., 2008).

Overall, there were higher levels of psychopathology among the group with a history of offending than the group without. Specifically in regards to impulsivity, state anxiety, somatic complaints, traumatic stress, paranoia, physiological symptoms of depression, irritability, thought disorder, antisocial behaviour, substance problems, aggression, and stress. It is important to identify the associated symptoms present among emerging adults with a history of offending as it generates a more complete picture of symptoms that are present beyond the BPD features that may be more readily apparent. This additional information aids in guiding tailored assessment protocols and prevention, intervention, and relapse prevention programs for both incarcerated non-incarcerated (i.e., probation) offenders with BPD features.

Hypothesis 3 stated that the group with a history of offending on average would have scores in the clinical range for specific associated BPD symptomatology and psychopathology as measured by relevant PAI clinical scales (i.e., drug problems, alcohol problems, anxiety, depression, paranoia) and two of the PAI treatment scales (i.e., aggression, suicidal tendencies). The findings provide support for Hypothesis 3. On average, the group with a history of offending demonstrated clinical levels of associated BPD symptomatology and psychopathology more frequently than the group without.
4.5 Abuse History and BPD Features Among the Group with a History of Offending

Hypothesis 4 stated that clinical levels of BPD features would be associated with an increased history of abuse (i.e., emotional, physical, sexual) in the group with a history of offending. The results of the current investigation do not support this hypothesis and are inconsistent with previous research (e.g., Taylor et al., 2009). The results suggest similar abuse experience across those with high and low BPD features among those with a history of offending. This result may be the consequence of a small sample size among the group with a history of offending and therefore fewer individuals with clinical levels of BPD features. An additional explanation may lie with the notion that prevalence of abuse history was high in the group with a history of offending overall and therefore differences could not be detected (i.e., limited range). Further research is required with a larger sample size to examine this relationship further.

4.6 Association Between BPD features and Criminal Offense Variables in the Group with a History of Offending

Hypothesis 5 stated that clinical BPD features would be associated with a greater number of offenses in the group with a history of offending. The current findings did not provide support for this hypothesis, which was inconsistent with prior emerging adult/adult offender research (e.g., Black et al., 2007). These findings may be impacted by a small sample size in the group with a history of offending. Further, these findings may be influenced by the nature of our sample (i.e., incarcerated versus non-incarcerated participants). Specifically, an incarcerated sample would likely have a greater number of offenses as compared to a non-incarcerated sample. Lastly, the results may be the product of utilizing an emerging adult sample, as no differences were detected in regards
to BPD features and number of offenses among adolescent/emerging adult offenders in Taylor et al. (2009). Emerging adults are younger and therefore may have had less time than adults to engage in multiple criminal behaviours (i.e., fewer arrested/charged offenses overall). The latter suggestion is inconsistent with crime trends. Specifically, 31% of all adult criminal court cases involved emerging adults (i.e., 18 to 24 years of age), which is alarmingly disproportionate as emerging adults make up only 12% of the adult population (Statistics Canada, 2008a). Further research is necessary to explore the relationship between clinical BPD features and number of offenses, particularly among a larger offender sample.

Differences were also examined among those with a history of offending in terms of the most serious offense arrested or charged for (i.e., status offense, violent offense, property offense, traffic offense, public order, and liquor law violations) across participants with high and low BPD features. Despite utilizing a heterogeneous group of emerging adults with a history of offending, no significant associations were detected in terms of type of offense and level of BPD features. This result is inconsistent with the emerging adult/adult offender literature that has highlighted an association between violent offenses and BPD features (e.g., De Barros & Serafim, 2008; Dixon et al., 2008; Hernandez-Avila et al., 2000; Logan & Blackburn, 2009; Ulrich et al., 2004; Warren et al., 2002; Warren & South, 2009). In contrast, the findings are consistent with the adolescent/emerging adult offender literature that has not found an association between BPD features and types of offenses (e.g., Taylor et al., 2009). Further research is required among the emerging adults age range to examine the association between type of offense and BPD features.
4.7 Sex Differences in BPD Features in the Group with a History of Offending

Hypothesis 6 stated that sex differences would be found among the group with a history of offending; specifically, we expected to find significantly higher BPD features among females with a history of offending as compared to males with a history of offending. The current findings demonstrate support for Hypothesis 6, however, the findings should be interpreted with caution due to the disproportionate ratio of females to males (36 females versus 7 males) in the current study. Females with a history of offending demonstrated increased elevations in BPD features than males. Specifically, females demonstrated increased elevations in affect instability/emotion dysregulation, identity problems, and negative relationships as measured by the PAI-BOR scale and subscales. Further, females demonstrated increased elevations in thoughts and feelings characteristic of BPD (i.e., feelings of emptiness, intense fears of abandonment, emotional dysregulation), and negative behaviours characteristic of BPD (i.e., self-harm, impulsivity, inappropriate expressions of anger, paranoia, instability in interpersonal relationships) as measured by the BEST. These results are consistent with the existing literature as females present with BPD features more frequently than males across various samples (e.g., community based and clinical samples; Maier et al., 1992; Zanarini et al., 1998). Overall, approximately 75% of adults diagnosed with BPD are female (APA, 2000). Disproportionate rates of BPD as a function of sex have been observed in the current sample and in the emerging adult/adult offender (55% versus 27%; Black et al., 2007) and adolescent/emerging adult offender extent literature (63% versus 45%; Becker et al., 2002). However, there was no significant difference observed in the current study across sex regarding self-harm on the PAI-BOR Self-Harm Subscale. Again, this result
may be the consequence of a small sample size for the group with a history of offending, and an unequal distribution of males and females.

4.8 Predictors of History of Offending

Hypothesis 7 stated that BPD features would be predictive of group membership (i.e., group with a history of offending versus group without a history of offending). Initial results provided support for Hypothesis 7. However, upon further examination it became apparent that additional risk factors (i.e., abuse history, substance problems) associated with offending in the literature may play a role in this relationship. History of abuse (Fagan, 2005; Kakar, 1996; Maxfield & Widom, 1996; Smith & Thornberry, 1995), drug problems (Bennett et al., 2008; BJS, 2006b), and alcohol problems (BJS, 2008; BJS, 1998), established risk factors for development of criminal behaviour, were also examined as potential predictors of group membership. When history of abuse, drug problems, and alcohol problems were included in the regression model, BPD features were no longer a significant predictor of group membership. The final model accounted for 26% of the variance in group membership. BPD features alone accounted for only 6% of the variance in group membership. Results suggest that alone PAI-BOR is a significant predictor of group membership, however, once abuse history, drug problems, and alcohol problems are involved PAI-BOR was no longer a significant predictor. Based on these results it appeared the relationship between PAI-BOR and history of offending may be mediated by history of abuse, drug problems, and/or alcohol problems.

Mediation analyses were completed to examine the aforementioned relationships. Results from the mediation analysis confirmed this notion. Specifically, abuse history, drug problems, and alcohol problems, each independently accounted for the relationship
between BPD features and history of offending. One potential explanation for this outcome is that individuals with BPD features and associated poor coping mechanisms, may abuse substances to cope with difficulties (i.e., interpersonal instability) and regulate emotions. In turn, substance problems are frequently associated with offending and therefore the two in combination may increase the likelihood of criminal activity.

In terms of abuse history, it appears inconsistent that abuse would mediate the relationship between BPD features and history of offending as abuse/maltreatment is a well supported etiological correlate in the development of BPD (e.g., Zanarini et al., 1997). One would assume that BPD would mediate the relationship between abuse and history of offending, however, this was not the case. Similarly, Christopher et al. (2007) examined personality pathology (i.e., BPD tendencies) as a potential mediator in the association between childhood sexual abuse victimization and later sexual abuse offending against others. Overall, childhood sexual abuse was significantly related to BPD tendencies, however, BPD tendencies did not mediate the relationship between childhood sexual abuse victimization and later sexual abuse perpetration. A similar pattern was observed in the current study. Specifically, abuse history mediated the relationship between BPD features and history of offending. Our findings may be partially explained by Linehan’s (1993) biosocial model of BPD. Linehan posits that individuals with BPD are born with specific biological predispositions (e.g., pre-existing emotional sensitivity), are exposed to invalidating environments (e.g., early parental abandonment, separation, loss, neglect; physical, sexual or emotional abuse), and in response are not able to regulate their emotions. Emotion dysregulation subsequently becomes a pervasive personality trait, a key feature of BPD. In turn, these individuals do
not learn how to adaptively problem solve. Most recently, Linehan and colleagues have examined trait impulsivity as a specific temperament that is biologically heritable (Crowell et al., 2009). These individuals with difficult temperaments (i.e., impulsive) may exacerbate existing negative environmental influences. With the current findings in mind, an individual may be born with trait impulsivity (a characteristic of BPD) in conjunction with an invalidating environment (e.g., abuse), in response are not able to appropriately regulate themselves or problem solve (e.g., self-injure to regulate mood, engage in criminal acts to meet their needs financially or emotionally). The latter may explain why some individuals experience BPD without a history of trauma (i.e., the invalidating environment may not necessarily be trauma). In turn, the latter may also serve to explain why some individuals with BPD do not engage in criminal activity (i.e., individual may not have problem solving difficulties that would lead to criminal behaviour). Further research is needed in this area to further examine what risk factors mediate the relationship between BPD and history of offending. In addition, it is important to know which specific BPD features may in fact mediate the relationship between BPD and history of offending (e.g., impulsivity, inappropriate expressions of anger, emotional dysregulation). A larger sample size would be required to complete this analysis. In turn, it would be beneficial to use the BPD module of the Structured Clinical Interview for DSM-IV diagnosis for Axis II (First, Spitzer, Gibbon, & Williams, 1997) to examine each BPD feature in detail in a mediation analysis.

4.9 Strengths, Limitations, and Future Directions

The current study was the first of its kind to examine BPD features using multiple valid measures (e.g., PAI; BEST) among a heterogeneous emerging adult male and
female sample with and without a history of offending. Types of offenses ranged for minor (e.g., status offenses) to serious (e.g., assault). The inclusion of a comparison group was a key strength of the current study as the extant adolescent/emerging adult offender and emerging adult/adult offender literature specifically examining BPD features has not previously included a comparison group. A further unique feature of this study was the inclusion of participants in the emerging adult age range. Exploring the aforementioned phenomena during this time period is critical given the previously noted disproportionate amount of crimes committed by this age range. Specifically, 31% of all adult criminal court cases involved emerging adults, 18 to 24 years of age, which is alarmingly disproportionate as emerging adults make up only 12% of the adult population (Statistics Canada, 2008a). It is important to examine criminal behaviour across the lifespan (e.g., emerging adult period) in order to clarify its etiology and what facilitates maintenance and continuance of such behaviour (i.e., recidivism).

Although this is a novel study, there were several limitations that require discussion. First, group membership was established based on self-reported history of an arrested or charged offense. As previously discussed self-report is a common method utilized in forensic research, however, there are several limitations involved with this method (e.g., potential over-reporting, under-reporting, reliance on memory and honesty). Future researchers should seek confirming information from an incarcerated sample where documented criminal history can be obtained. Second, the current sample was comprised entirely of undergraduate students. Although the sample was divided into two groups based on the presence or absence of a self-reported history of offending, the group with a history of offending may not be representative of emerging adults with a history of
offending in the community (e.g., different levels of education, financial situation). In turn, the results of the current study may not entirely generalize to an incarcerated sample, although many findings were consistent with the existing offender literature utilizing incarcerated samples. However, as previously noted, it is important to understand psychopathology in relation to offending outside of an incarcerated environment as specific symptom presentations may arise in response to such an environment. Third, our sample had a disproportionate ratio of female to male participants (i.e., 155 females versus 32 males). Specifically, within the group with a history of offending the ratio of females to males was disproportionate (36 females versus 7 males). This distribution may have impacted the findings as previous research indicates that females are more likely to present with BPD features than males. However, Taylor et al. (2009) examined BPD features among a strictly male incarcerated serious offender sample demonstrating similar results. In addition, it was hypothesized that females with a history of offending would present with more elevated BPD features than males with a history of offending. Results supported the sex difference hypothesis, however, a more equivalent sex ratio would be preferred for future research. Fourth, the group with a history of offending was small (n = 43). Future research should utilize a larger sample size for the group with a history of offending. In particular, equivalent sample sizes would be preferred for the two groups (with and without a history of offending). Fifth, the sample was largely Caucasian. It would be beneficial for future research to have a more varied ethnic distribution in order to facilitate examination of the potential association between ethnicity and history of offending among emerging adults. Sixth, although the BEST is a well established measure, an alternative second measure should
be utilized in future research on non-clinical samples. The BEST subscale C was not a good fit for use in a non-clinical population as it inquires about treatment adherence and most non-clinical samples have no or very limited treatment experience. The Personality Diagnostic Questionnaire - 4 - BPD scale (PDQ4-BPD; Hyler, 1994) may be an adequate measure for an undergraduate sample. Finally, the current study relied on self-report via a web-based data collection methodology. This type of study could be strengthened by including a clinical interview, (i.e., Structured Clinical Interview for DSM-IV diagnosis for Axis II; First et al., 1997) to establish a diagnosis, albeit the focus in the current study was on exploring BPD features dimensionally. Furthermore, there are several limitations associated with web-based data collection (e.g., random responding, potential for multiple submissions by the same participant, software issues, falsification of participant identity). Despite web-based data collection limitations numerous procedures were put in place to protect against the potential of random responding (e.g., validity scales within measures) and multiple submissions (e.g., statistical software that has the ability to identify duplicate entries; SPSS 18.0).

4.10 Scientific and Clinical Implications

The results of the study offer empirical evidence in regards to BPD symptomatology within an emerging adult group with a history of offending, estimated prevalence, and associated characteristics (e.g., type of criminal offense, number of offenses), therefore advancing current understanding of this unique population. In sum, BPD features (i.e., affect instability, negative relationships, self-harm, inappropriate expression of anger, feelings of emptiness, paranoia, impulsivity, intense fears of abandonment), associated BPD symptomatology (i.e., impulsivity, paranoia, aggression,
substance problems), and psychopathology (i.e., state anxiety, traumatic stress, somatic complaints, physiological symptoms of depression, thought disorder, irritability, antisocial behaviours, stress) were more elevated in the group with a history of offending than the group without. There was no relationship detected in the group with a history of offending in terms of BPD features (high versus low) and number or types of offenses. Comparisons of BPD features between groups of emerging adults with and without a history of offending contributes to the current understanding of how BPD may influence criminal behaviours and, possibly, recidivism. Specifically, BPD features (e.g., impulsivity, emotion dysregulation, intense expressions of anger) may lead to the engagement in the criminal act itself (e.g., individual cannot self-regulate), not necessarily the type of criminal act. Further research is needed to verify this possibility.

The current findings have important clinical implications. First, in an emerging adult, non-incarcerated group with a history of offending significant levels of psychopathology were present. These findings alone highlight a group of individuals who require access to appropriate mental health services. Second, our findings point to specific variables that predict group membership (i.e., BPD features, abuse history, substance problems). The latter draws attention to areas that should be considered when developing assessment protocols and prevention, intervention, and relapse prevention programs for both incarcerated and non-incarcerated (e.g., those on probation or newly released from corrections). Third, current findings are supportive of the utility of existing interventions (or possibly modified existing interventions) such as Dialectical Behavior Therapy (DBT; the empirically supported intervention for BPD) that can be implemented within the corrections system (i.e., Trupin et al., 2002). Current findings and subsequent research
can help to inform the modification and/or development of innovative prevention, intervention, and relapse prevention programs better equipped to treat emerging adult offenders demonstrating BPD tendencies (e.g., DBT adapted to forensic settings). Ultimately, improved assessment of BPD and the application of appropriate prevention and intervention programs may aid in decreasing recidivism rates, and, therefore, costs to society.

Re: Exploring Borderline Personality Disorder Features Dimensionally Among Young Adults with a History of Offending (File #49S1011)

Please be advised that the University of Regina Research Ethics Board has reviewed your proposal and found it to be:

☐ 1. APPROVED AS SUBMITTED. Only applicants with this designation have ethical approval to proceed with their research as described in their applications. For research lasting more than one year (Section 1F), ETHICAL APPROVAL MUST BE RENEWED BY SUBMITTING A BRIEF STATUS REPORT EVERY TWELVE MONTHS. Approval will be revoked unless a satisfactory status report is received. Any substantive changes in methodology or instrumentation must also be approved prior to their implementation.

☐ 2. ACCEPTABLE SUBJECT TO MINOR CHANGES AND PRECAUTIONS (SEE ATTACHED). Changes must be submitted to the REB and approved prior to beginning research. Please submit a supplementary memo addressing the concerns to the Chair of the REB.** Do not submit a new application. Once changes are deemed acceptable, ethical approval will be granted.

☐ 3. ACCEPTABLE SUBJECT TO CHANGES AND PRECAUTIONS (SEE ATTACHED). Changes must be submitted to the REB and approved prior to beginning research. Please submit a supplementary memo addressing the concerns to the Chair of the REB.** Do not submit a new application. Once changes are deemed acceptable, ethical approval will be granted.

☐ 4. UNACCEPTABLE AS SUBMITTED. The proposal requires substantial additions or redesign. Please contact the Chair of the REB for advice on how the project proposal might be revised.

Dr. Bruce Plouffe

cc: Kristi D. Wright – Psychology Department

** supplementary memo should be forwarded to the Chair of the Research Ethics Board at the Office of Research Services (Research and Innovation Centre, Room 109) or by e-mail to research.ethics@uregina.ca

Introduction: You, a current psychology student of the University of Regina, are being invited to take part in an online study to see how personality might differ between young adults with and without a history of criminal behaviour. Students recruited through the psychology participant pool will be given a 2% course credit for two hours of participation. The use of the research participant pool to recruit participants in return for course credit is a common practice in psychological research. Course credit obtained by students can be used to enhance grades in participating psychology courses.

Purpose: The primary purpose of the present study is to examine whether young adults with a history of offending differ from those without a history of offending in terms of personality features and associated characteristics.

Voluntary Participation: Participation in this study is entirely voluntary, so it is up to you to decide whether or not to take part in this study. Before you make a decision, though, it is important for you to understand what the research involves. This consent form will tell you about the study, the purpose of the research, what will happen during the study, and the possible risks, and benefits. If you do decide to take part in this study, you will be asked to sign this consent form. Even after signing the informed consent form, you can choose to drop-out at any time, refuse to answer any questions, as well as request that the information collected not be used. Lack of participation will not result in any negative consequences (e.g., affecting grades, services provided by the university) for yourself.
**Who is conducting the study:** The Primary Investigator is Chelsea A. Delparte, B.A. Hons. She is a Master’s student in Clinical psychology at the University of Regina, Department of Psychology. This project is part of a Master’s thesis required for partial fulfillment of the University of Regina’s Master’s program.

**Specific Procedures:** Before you agree to participate, we would like to provide you with information about the procedures involved in the study so that you can make an informed decision. You will be asked to read and complete an informed consent form. Following consent, you will be asked to complete a self-report form about history of criminal behaviour and personal characteristics (2 sections, 42 questions, each question containing sub-questions), and fill out six questionnaires asking questions about your personality, feelings, and behaviour. Total time is expected to be approximately 2 hours, however it may take less time.

**Benefits:** No direct benefit can be guaranteed. However, it is anticipated that the findings from this investigation will aid in a better understanding of the relationship between personality and other feelings and behaviour that may influence criminal activity. Although participants may not benefit directly from this study, it has the potential to greatly improve our understanding of young adult criminal behaviour.

**Risks:** There are no anticipated risks in terms of participating in this investigation.

**Confidentiality:** Any information gathered during the data collection process is strictly confidential and will be used for research purposes only by the University of Regina. All information collected will be made anonymous. The electronic file will not contain any identifying information. The consent forms (containing the participant name) will be kept separate from the participant responses. No participant names will be put on the questionnaires, the self-report offending form, or the demographic form. All of the information that we collect will be stored on a lap top/lab computer (requiring an access code) at the University of Regina in the primary investigator’s research lab for an indefinite amount of time.

**Use of Survey Monkey:** It is also important for you to know that "Survey Monkey", a web-survey company that is located in the USA, is the host of this on-line research. This company is subject to U.S. laws; in particular, the US Patriot Act that allows authorities access to the records of internet service providers. Survey Monkey's servers record incoming IP addresses - including that of the computer that you use to access the survey. However, no connection is made between your data and your computer's IP address. If you choose to participate in the survey, you understand that your anonymous responses to the survey questions will be stored and accessed in the USA.
As An Internet-Based Study, What Are the Possible Breaches to Confidentiality and Security: As an Internet-based research study, there is a very small risk that participation may compromise your privacy. A description of these risks follows:

1. To prevent multiple submissions from the same source, this study will record your computer's Internet address, which is a special identification number assigned to your computer by your Internet Service Provider. This information will be stored in a file until the research is completed, at which point the file will be deleted. This information will not be used to identify individuals.

2. The electronic submission of your responses may, in rare instances, be intercepted by unauthorized third parties using sophisticated tools. The likelihood of this occurring is extremely rare and is a risk for anyone when using a computer generally.

3. When using a computer that is connected to the Internet to access websites, information about the websites that you visit will be stored in your Internet browser's history list and in its disk cache. This can be resolved by clearing the history list and disk cache. Note, however, that responses to the survey are only stored temporarily on your computer until you close your browser window. Therefore, after you submit your responses, your computer will automatically delete this information.

4. Given the manner in which this study is being conducted, all of the survey responses will be sent immediately to the survey software website. The survey software website then stores the responses in a private folder accessible only by the primary researchers. All responses will be downloaded weekly and kept in a secure location by the primary researcher until the conclusion of the study. The data stored on these disks cannot be associated with you or your Internet address.

Contact Information: If you have any questions, feedback or comments about the research study or the results of the research study, please feel free to contact the Primary Investigator, Chelsea A. Delparte at (306) 337-3339 (e-mail: delpartc@uregina.ca) or the supervisor of the research project Dr. Kristi D. Wright at (306) 585-4180 (e-mail: kristi.wright@uregina.ca). A summary of study results will be available once all data have been collected and analyzed. This will likely take over a year. If you have any further questions regarding research findings, please feel free to contact us.

If you have any questions or concerns about your rights as a research participant, you may contact the Chair of the Research Ethics Board at (306) 585-4775 (email: research.ethics@uregina.ca).

Participant Consent to Participate:

Are you 18 years of age or older?

Yes
Have you read and understood the information page?
Yes

Do you freely and voluntarily consent to take part in the research?
Yes

Completion of this online questionnaire implies consent to participate in this project. If you have questions you may e-mail the primary investigator, Chelsea Delparte, at delpartc@uregina.ca or, you may contact her supervisor, Dr. Kristi Wright, at kristi.wright@uregina.ca

You may also contact the Chair of the Research Ethics Board at the University of Regina at (306) 585-4775 or by e-mail: research.ethics@uregina.ca
Appendix C

Demographic Information

1. What is your sex?
   _____ Male   _____ Female

2. How old are you?

   Age: ________

3. What is your date of birth? (Month, Day, Year)

   Birthday: _____ MM  _____ DD  _____ YY

4. What is your ethnicity?

   _____ White/Caucasian   _____ Black/African   _____ Hispanic

   _____ Asian            _____ Aboriginal/First Nations   _____ Middle Eastern

   _____ Mixed Ethnicity  _____ Other (please specify)

5. What is your highest level of education?

   University: _____ first year  _____ second year  _____ more then 4 years

   _____ third year  _____ fourth year

6. What is your current relationship status?

   _____ Single  _____ Divorced  _____ Common law/cohabiting

   _____ Married  _____ Separated  _____ Dating

   _____ Widowed  _____ Other (please specify)

7. What is your current employment status? (Select all those that currently apply)

   _____ Employed-full time  _____ Employed part-time  _____ Employed

   _____ Student  _____ On disability  _____ Other (please specify)
8. What is your current family size? 

number

9. What is your current household income?

_____ Less than 30,000  _____ 30,000-49,999  _____ 50,000-99,999 

_____ 100,000-499,000  _____ greater than 500,000

10. What are your current living arrangements?

_____ Living alone  _____ Living with one or more roommates

_____ Living with one or both parents  _____ Living with spouse/partner 

_____ Living with spouse/partner and children  _____ Living with children 

_____ Living with extended family  _____ Other (please specify)

11. What is your parents’ current relationship status?

_____ Married  _____ Divorced  _____ Separated  _____ Other (please specify)

12. Have you ever experienced emotional abuse?

Yes

No

13. Have you ever experienced sexual abuse?

Yes

No

14. Have you ever experienced physical abuse?

Yes

No

15. If you have answered yes to questions 12, 13, or 14, then at what age did the abuse occur?
16. For how many years did the abuse occur?

Years _____
Appendix D

Self-Report of Offending – Revised

Date: ________ ________ ________

This questionnaire asks about things that people sometimes do. Remember, at the beginning of the study, I told you about the special protection to ensure your privacy? We will ensure that no one will see or find out what your answers are in this study. No one except our research staff will ever see them. Your answers can never be seen by police, the courts, your parents/guardian, or anyone else. This questionnaire is completely anonymous and will only be attached to your questionnaire package which will exclude all identifying information.

These questions will inquire about some things that people do. First, indicate whether you have ever done any of these things and if so answer the questions that follow (e.g., how many times have you done the thing, were you ever arrested for doing the thing, were you ever convicted of doing the thing, when was the last time you did the thing, was there a sentence...).

Please provide your best estimate or guess of the exact number of times you have done each thing.

DO NOT INCLUDE ANY NAMES OR IDENTIFYING INFORMATION (e.g., student number, address, phone number, email address) ON THIS QUESTIONNAIRE
Section I.

1A. Have you ever carried a hidden weapon?

1. Yes — Go to Q. 1B
2. No — Go to Q. 2A

1B. How many times have you done this?

# of times

1C. Were you ever arrested for this?

1. Yes — Go to Q. 1D
2. No — Go to Q. 2A

1D. Were you ever charged for this?

1. Yes — Go to Q. 1E
2. No — Go to Q. 2A

1E. Were you convicted of this?

1. Yes — Go to Q. 1F
2. No — Go to Q. 2A

1F. How many times were you convicted of carrying a hidden weapon?

# of times

1G. How old were you when you were first convicted of this?

Age

1H. How old were you when you were last convicted of this?

Age

1I. Was there a sentence for carrying a hidden weapon?

1. Yes — Go to Q. 1J
2. No — Go to 2A
1J. What was your most recent sentence for carrying a hidden weapon? (e.g., fine, probation, community service, placement in a correctional facility)

__________________________
Sentence

1K. How many times have you been sentenced for carrying a hidden weapon?

**Always/Almost**

1. I plan tasks carefully.
2. I do things without thinking.
3. I make up my mind quickly.
4. I am happy-go-lucky.
5. I don't "pay attention."
6. I have "racing" thoughts.
7. I plan trips well ahead of time.
8. I am self controlled.
9. I concentrate easily.
10. I save regularly.
11. I "squirm" at plays or lectures.
12. I am a careful thinker.
13. I plan for job security.
15. I like to think about complex problems.
16. I change jobs.
17. I act "on impulse."
18. I get easily bored when solving thought problems.
19. I act on the spur of the moment.
20. I am a steady thinker.
21. I change residences.
22. I buy things on impulse.
23. I can only think about one thing at a time.
24. I change hobbies.
25. I spend or charge more than I earn.
26. I often have extraneous thoughts when thinking.
27. I am more interested in the present than the future.
28. I am restless at the theater or lectures.
29. I like puzzles.
30. I am future oriented.

SCORING: zero for answers in the first column, 1 for answers in the second column, 2 for answers in the third column, 3 for answers in the fourth column. The scoring of positive items is reversed. Possible range of scores is zero to 60, with the higher scores indicating the presence of more symptomatology.

Project Title: Exploring Borderline Personality Disorder Features Dimensionally Among Young Adults with a History of Offending

Thank you for taking the time to participate in this study on personality in relation to criminal behaviour. This study constitutes the Master's thesis of Chelsea Delparte and your contribution is appreciated.

A specific cause for emerging adult offending has yet to be established; however, the empirical literature has highlighted certain personality characteristics that appear to be present in both adolescent and adult offenders. Specifically, personality features symptomatic of borderline personality disorder (BPD) repeatedly appear throughout adolescent/young adult and adult offender populations (e.g., difficulty regulating emotions, suicidal thoughts, self-harming behaviours, impulsivity). To date, the best study to assess specifically for BPD features within an adolescent/young adult incarcerated offender sample was conducted by Taylor, James, Reeves and Kistner (2008). Taylor et al. examined the association between BPD features and increased clinical and social problems among male adolescent/young adult offenders. Results demonstrated that male adolescent/young adult offenders with high BPD features displayed an increased amount of psychopathology, worse social relations, and a greater history of trauma than adolescent/young adult male offenders without BPD in the same facility. Although this is an important study, there are some methodological limitations (e.g., assessment of BPD features with a single measure, using only male serious offenders, comparison to only other offenders). Our research seeks to improve on these methodological limitations examining BPD features among male and female young adults with and without a history of offending.

The researchers are seeking to determine the relationship between BPD features and criminal behaviour. To our knowledge no studies have examined BPD in relation to young adult criminal offending among an undergraduate university sample. Specifically, we aim to explore BPD features in relation to number of offenses and types of offenses among a heterogeneous young adult undergraduate sample with a history of offending.

If young adults with a history of offending demonstrate significantly more BPD features than those without then this may facilitate improved assessment of BPD symptoms within criminal populations. Improved assessment will lead to the development and implementation of appropriate treatment programs which it is anticipated will aid in decreasing recidivism rates.

Thank you for your participation. If you are interested in the results of this study please contact the primary investigator, Chelsea Delparte (delpartc@uregina.ca), who will arrange for the information to be sent to you once the study is complete. Questions are welcomed, and any concerns that you may have are important and should be addressed.
